There is no received view about that. But the leading physicalist strategy for dealing with the second horn of Hempel's dilemma is to maintain that the physics that is fact true of our world will be a recognizable descendant of current physics (Pettit, 1993; Lewis, 1994; Jackson, 2007). That is an a posteriori claim that could prove false. Further, it is not preposterous to think that current physics may be very distant from the ideally completed physics that it is true of our world. It could turn out that the ideally completed physics will be as different from current physics as the air, earth, fire, and water chemistry of antiquity is from quantum chemistry. It is generally acknowledged, however, that the doctrine of physicalism should be an empirical doctrine that could prove false. So, it is no objection to this characterization of physicality that a version of physicalism that deploys it could turn out to be false. Moreover, many contemporary physicalists are willing to maintain that physicalism is true only if the physics that is in fact true of our world will be a recognizable descendant of current physics.

They are willing to do so, because they take the empirical case for physicalism to rely, in part, on the success of the atomic theory of ordinary matter (including living matter), the success of quantum mechanics in explaining chemical bonding, the success of organic chemistry in explaining certain biological phenomena, and the fact that it appears that all of the fundamental forces of nature can be found below the level of the atom. They maintain that, on the evidence, we are wholly composed of cells, which are composed of molecules, which are composed of atoms, which are composed of electrons, protons, and (with the exception of hydrogen) neutrons, and that neurons and protons are composed of quarks. They maintain further that, on the evidence, the computational processes that occur in our brains are implemented by neurophysiological processes, which are implemented by chemical processes, which in turn are implemented by quantum mechanical processes involving subatomic particles. Moreover, they maintain that the objective probability of the physical movements of any living organism or sentient creature, and any movement of any of its physical parts, will be wholly determined (or their objective probability will be wholly determined) by prior physical events (perhaps those occurring on some cross section of the backward light cone of the physical movements in question). These considerations do not settle whether physicalism is true. A property or attribute dualist need not deny these claims. But considerations of overall coherence and simplicity of total theory are also invoked in defense of physicalism (Smart, 1959; Hill, 1991; Poland, 1994; Loewer, 2001; Melnyk, 2003; McLaughlin, 2010). Whether physicalism can be adequately defended is not a topic of this article. The important point for present purposes is just that physicalism is defended, in part, by appeal to the successes of current physical theory.

The notion of a recognizable descendant of current physics is of course quite vague. But it is not so vague as to be useless. And it can be made more precise. Thus, it can be claimed that completed physics will be a recognizable descendant of current physics only if all ordinary matter, including the matter that makes us up, is wholly composed of atoms, which are more fundamentally physically constituted, and that all of the fundamental forces of nature are at work at a scale below the level of atoms (though, of course, not only below that scale). No stand need be taken on, for example, whether fundamental physical reality will turn out to be particle-like, or instead a matter of vibrating strings, or a matter of branes. Also, it can be allowed, for instance, that the completed physics may take space-time to be nonfundamental yet still be a recognizable descendant of current physics. Even the condition that all fundamental forces are ones that can be found below the level of the atom need not be insisted upon. Suppose that there turn out to be some fundamental chemical forces exerted only at the scale of certain atoms and above, so that there are fundamental chemical forces in addition to force of gravity, the electromagnetic force, the strong force, and the weak force. (The chemical forces invoked in current chemistry, such as van der Waal forces and dipole–dipole forces, are not fundamental forces; they are electromagnetic in origin.) Some physicalists will maintain that that alone would not be a sufficient break from current physics to render physicalism false. There is thus some flexibility in which family resemblances should be focused on, and some resemblances may be given more weight than others. Although there is such flexibility about how the completed physics that is true of our world should resemble current physics, rational debate about physicalism can proceed so long as it is reasonably clear what family resemblances to current physics are supposed to be relevant in the context of the debate.

To fix our ideas, it will often be assumed in what remains both that the physical is whatever would be posited by the completed physics that is in fact true of our world, and that that physics will be a recognizable descendant of current physics. Although this notion of physicality is vague and context dependent, it is sufficiently determinate in content to allow rational debate about the sorts of matters over which debates about physicalism and its alternatives typically center.

Formulating Physicalism and Distinguishing It from Its Alternatives

'Physicalism' is a technical term of metaphysics. Proponents of physicalism must tell us what the doctrine is. As noted above, there is no consensus about how, exactly, the doctrine should be formulated. Since physicalists are persons who hold the doctrine of physicalism, it is thus somewhat uncertain who, exactly, counts as a physicalist, even given the specific conception of the physical embraced above. Here 'physicalist' will be used to mean self-professed physicalist.

It is generally acknowledged that the doctrine of physicalism should be an empirical doctrine, that is, that it should be both contingent and a posteriori. There is a physicalist doctrine called 'a priori physicalism', but it is misleadingly so called,

because it does not entail that physicalism is a priori. It is, rather, roughly, the doctrine that all truths follow a priori from physical truths. Many physicalists deny that the entailments must be a priori, rather than just metaphysically necessary. They are labeled 'a posteriori physicalists'. But both a priori and a posteriori physicalists agree that physicalism itself is a posteriori (Jackson, 2007; McLaughlin, 2007).

Type physicalism is the thesis that every type or kind of property, and every type or kind of entity (object, event, state, process, or field, etc.) is a physical type. The relevant identity claims, it is maintained, will typically be only a posteriori knowable.

Physicalists typically take type physicalism to be too strong a thesis to require for physicalism. Many argue that the special sciences of biology, psychology, economics, anthropology, and sociology all posit kinds of properties and objects that would not be posited by any physics that is a recognizable descendant of current physics. Yet they want to be realists, rather than eliminitivists (Stich, 1999), about such kinds.

Token physicalism is the thesis that every concrete particular is physical. It is implied by type physicalism, since if every type is physical, any token of any type will be physical. But it does not imply type physicalism. Thus, even if, as seems to be the case, the kind *person* is not a physical kind, if every particular person is a complex physical body, then the existence of persons (instances of the kind *person*) is compatible with token physicalism.

Some physicalists maintain that even token physicalism is too strong a thesis to require for physicalism. The weaker claim is sometimes made that every concrete particular is either physical or wholly constituted by physical things at some level of aggregation (Hellman and Thompson, 1975). Thus, it is sometimes maintained, for instance, that although persons have bodies, they are not identical with their bodies, since persons and their bodies have different persistence conditions (Baker, 2000). A person can cease to exist, even when the person's body continues to exist (e.g., at permanent brain death). Indeed, they typically hold as well that human bodies are not identical with collection of physical particles, since bodies and such collections have different persistence conditions: the same body can lose and acquire physical particles with the result that it is constituted by a different collection. They maintain, however, that persons (at a time) are wholly constituted by their bodies (at the time in question), and so do not have immaterial minds, or immaterial souls, or entelechies. Indeed, they typically claim that persons are wholly constituted (at a time) by their microphysical constituents (at that time), and so that the existence of persons should be compatible with physicalism properly formulated.

Some physicalists maintain that it is too strong even to require for physicalism that every concrete particular is either physical or wholly constituted by physical things. They maintain that there are, for instance, Individual Retirement Accounts (IRAs) (and the like), and that they are neither physical nor constituted by physical things, but that their existence should be compatible with physicalism, provided that what IRAs there are and their pattern of distribution are appropriately supervenient on the physical (Haugeland, 1984). It is not required, they claim, that there are in principle identifiable physical bits of our world that minimally constitute IRAs.

It is also widely held that token physicalism is too weak to characterize physicalism, because it is compatible with the existence of nonphysical properties or kinds that fail to be appropriately ontologically dependent on the physical. Token physicalism is, for instance, compatible with the view that mental properties are nonphysical properties that figure in contingent laws of nature that are also fundamental laws, fundamental in the way that the law of gravity is fundamental in Newtonian mechanics, and that Schrödinger's equation is fundamental in non-relativistic quantum mechanics. No recognizable descendant of current physics would posit contingent fundamental psychophysical laws. If there are such laws, then the mental properties cited in them are contingently, ontologically emergent from the physical (Broad, 1925; McLaughlin, 1992). The thesis that mental properties are contingently ontologically emergent from the physical, a thesis that has some currency for certain mental properties (e.g., qualia, the qualitative aspects of experiences), is compatible with the thesis that every concrete particular is or is wholly constituted by physical concrete particulars. But such a property emergence view is nowadays widely held to be incompatible with physicalism, and so to be an alterative to physicalism. Token physicalism seems both too weak and too strong to count as physicalism in the sense that many self-professed physicalists have in mind.

One of the main reasons given in the literature for not requiring for physicalism that all properties are physical properties is that physicalism should allow that there are functional properties (Van Gulick, 2009). A functional property is a second-order property of having some property or other whose instances occupy or play a certain functional role. A functional role will mainly include a causal role (but may also include certain counterfactual dependencies that are not causal), typically a role both as cause and as effect. For a property to have a causal role is for its instances (its exemplifications) to have or to tend to have certain causes and/or effects. The causal role can be a conditional role as cause and effect: instances of the property may have or tend to have certain kinds of causes under certain kinds of conditions, and certain kinds of effects under certain kinds of conditions. A first-order property that plays the role in question is said to 'realize' the functional property; thus the relation of realization in this functionalist sense is that of role occupancy. (There are other notions of realization in the philosophical literature. See, e.g., Shoemaker, 2007.) If more than one first-order property plays the role in question, then the property is multiply realizable. A functional property may be multiply realizable by physical properties, so fail to be identical with any of its physical realizers. Moreover, a functional property may even be such that it is at least metaphysically possible for it to be realized without being realized by any physical property. That is to say, it may be such that there is a metaphysically possible world in which it is realized without being realized by any physical property. Perhaps there is a metaphysically possible world in which certain functional properties are realized in beings wholly composed of ectoplasm. Such functional properties are not physical properties. But it is fairly widely held that physicalism should nevertheless accommodate some such functional properties.

Whether physicalism can accommodate functional properties is taken to be a crucial issue since many philosophers

embrace the role-functionalist view that mental properties (or at least certain kinds of mental properties such as being a belief, desire, intention, and the like) are functional properties, that is, second-order properties of having some property or other that occupies a certain functional role. Proponents of the view that mental properties are functional properties maintain that their view should be compatible with physicalism properly formulated, even if the functional properties in question are not only multiply realized by physical properties in worlds with our laws of nature, but also such that they can be realized without being physically realized in certain worlds without our laws of nature, worlds that are thus nomologically impossible, yet nevertheless metaphysically possible. They maintain that, in part, because functional properties are not fundamental properties, but rather derivative ones. Something will have a functional property in virtue of having a property that realizes it. In that sense, they are always grounded in other properties, namely their realizers.

Realization functionalism is the doctrine that every instantiated property is physical or realized by a physical property (Melnyk, 2003). This captures instantiated functional properties, provided that they are realized by physical properties whenever they are realized. The doctrine is silent, however, about uninstantiated properties. It is compatible with the existence of uninstantiated, contingent, functional properties that would not be realized by physical properties were they instantiated. Indeed, it is compatible with the existence of contingent properties that are neither physical nor functional, provided that they are never instantiated; for it does not rule out that there are fundamental laws of nature that cite nonphysical, nonfunctional properties, so long as those laws of nature are never instantiated. If there are fundamental, yet uninstantiated nonphysical laws of nature, it might be the case that although every object is physical or wholly composed of physical entities and all instantiated properties are physical properties or realized by physical properties, it is an accident that this is so; for there might be a fundamental law of nature according to which, were certain physical conditions to obtain (that never in fact obtain), wholly disembodied spirits would come into existence. That is, the laws of nature might be such that a certain brew of physical ingredients would cause to come into existence disembodied spirits not constituted by physical entities, even though, by chance, the physical ingredients in question have never come together into that brew (Witmer, 2001). Physicalism should require that even uninstantiated properties, if they are contingent existents, be appropriately ontologically dependent on the physical. Still, though, the fact that it could turn out to be the case that whenever something has a functional property, it has it in virtue of having a physical property that realizes it leads physicalists to maintain that a properly formulated physicalism can countenance functional properties.

How must the nonphysical be ontologically dependent on the physical for physicalism to be true? One leading view is that it is a minimal requirement that the nonphysical appropriately supervene on the physical, so that there can be no nonphysical difference of any sort without a physical difference. The kind of supervenience in question is widely taken to be global supervenience, more specifically, strong global supervenience (McLaughlin and Bennett, 2011). Global supervenience theses invoke possible worlds, that is, complete ways the world might be. The following is a leading formulation of such a supervenience definition of physicalism: physicalism is true if and only if any minimal physical duplicate of our world is a duplicate *simpliciter* of our world (Jackson, 1998). A possible world is a duplicate of our world just in case it is exactly like our world in every physical respect, particular and general: in what kinds of physical entities there are, in how instances of them are distributed in space-time, in what physical properties and relations there are, in how they are distributed over particulars, in what physical laws of nature there are, and so on. A possible world is a minimal physical duplicate of our world just in case it includes nothing other than what it must, of metaphysical necessity (the strongest kind of necessity), include to be a physical duplicate of our world. A duplicate *simpliciter* of our world is any possible world that is exactly like our world in every respect whatsoever. (Lewis (1983) and Chalmers (1996) offer closely related, though nonequivalent, definitions of physicalism that also appeal to global supervenience. Most of what is said below about physicalism in the sense just defined will apply to their definitions of physicalism as well.) On this formulation, the existence of functional properties is compatible with physicalism, provided that any minimal physical duplicate of our world would include exactly the functional properties included in our world, and would have exactly the same worldwide pattern of distribution of those functional properties as in our world. Role functionalists about the mental that are physicalists should maintain that that condition is met for the functional properties that are mental properties.

Our world is trivially a physical duplicate of itself. Our world is the actual world, and so a possible world since what is actual is possible (though not conversely). And our world is a duplicate simpliciter of itself, for the trivial reason that everything is a duplicate simpliciter of itself – that is, everything is like itself in every respect whatsoever. It follows that our world is a physical duplicate of itself. It is, however, by no means trivial whether our world is a minimal physical duplicate of itself; for it is by no means trivial whether our world contains more than it must, of metaphysical necessity, contain to be a physical duplicate of itself. It might, for example, include contingent immaterial minds or disembodied spirits. If it does, then since a world that is a minimal physical duplicate of our world would not include such immaterial minds or disembodied spirits, it is not the case that any minimal physical duplicate of our world will be a duplicate simpliciter of our world. If, then, physicalism is true if and only if any minimal physical duplicate of our world is a duplicate simpliciter of our world, it would follow that physicalism is false. Physicalism is also false if our world includes contingent, fundamental psychophysical emergent laws of nature. For given that the laws are contingent and fundamental, a world that is a minimal physical duplicate of our world will not include them, and so will fail to be a duplicate simpliciter of our world. Indeed, all of the leading alternative doctrines to physicalism entail that it is false that any minimal physical duplicate of our world is a duplicate simpliciter of our world, and so are incompatible with physicalism so understood.

The formulation of physicalism in question does not entail that any physical duplicate of our world is a duplicate simpliciter of our world. Physicalism, so formulated, is consistent with its being the case that there is a physical duplicate of our

world that includes, in addition to what it must include to be a physical duplicate of our world, certain nonphysical entities, properties, relations, or laws of nature. It is taken to be a virtue of the characterization of physicalism in question that it is compatible with the possibility of a physical duplicate of our world that include such 'extras', that is, such extra entities, properties, relations, or laws of nature since that seems to be a metaphysical possibility. Our world's being the complete way it is physicality, it is claimed, is, for instance, compatible with there being a realm of disembodied spirits (or spirits composed of ectoplasm). A physical duplicate of our world can include such a realm of spirits. But the thesis that any minimal physical duplicate of our world is a duplicate simpliciter of our world requires that our world not include such a realm.

This formulation of physicalism is fairly widely taken to state a conceptually necessary condition for physicalism. It is, however, also widely taken to fail to state a conceptually sufficient condition for physicalism. For the condition that any minimal physical duplicate of our world is a duplicate simpliciter of our world is conceptually compatible with there being a necessarily existing God (Jackson, 1998). Any doctrine deserving of the name 'physicalism' should be incompatible with the existence of a God, necessary or contingent. (One exception is the version of pantheism according to which God is just the universe.) Indeed, physicalists must deny that it is even metaphysically possible for there to be a necessarily existing God. For, on a widely held assumption about metaphysical necessity, if it is metaphysically possible for a necessarily existing God to exist, then it is metaphysically necessary that it is possible for a necessarily existing God to exist, and so such a God exists in every metaphysically possible world, and thus exists our in our world. The necessary God objection to this version of physicalism does not rely on the assumption that such a God is indeed metaphysically possible. If a necessarily existing God is even conceptually possible (coherently conceivable), then the condition that any minimal physical duplicate of our world is a duplicate simpliciter of our world fails to be a conceptually sufficient condition for physicalism's being true.

There is no consensus in the literature about how to handle this problem. A natural move, which is to the best of the author's knowledge not made in the literature, is to avoid the problem by defining physicalism as the conjunction of the thesis that any minimal physical duplicate of our world is a duplicate simpliciter of our world and an appropriate statement of naturalism, the doctrine characterized earlier. The idea is that the naturalism conjunct would rule out the possibility of a necessary God. It should be noted in support of this move that it is natural to think of physicalism as a kind of naturalism. A proper formulation of naturalism is itself, however, no trivial matter; the one given earlier was only rough and ready. But the idea is that what differentiates the species physicalism from the genus naturalism is the condition that any minimal physical duplicate of our world is a duplicate simpliciter of our world.

There is, though, a second problem case that is cited in the literature to show that the condition that any minimal physical duplicate of our world is a duplicate simpliciter of our world fails to state a sufficient condition for physicalism. And the second problem case is compatible with naturalism. The problem is the possibility of 'blockers' (Hawthorne, 2002). As noted above, the minimality thesis allows that a physical duplicate of our world could include 'extras', including extra properties and laws. Suppose, then, that in our world and indeed in any possible world that is a minimal physical duplicate of our world, whenever something has a certain physical property P, it has a certain mental property M. Suppose further that the relationship between having P and M is weaker than metaphysical necessitation, so that there are possible worlds in which when something has P and also has a certain property B, a property that nothing in our world has (and indeed that does not even exist in our world, if properties are contingent existents), then that something lacks M. In that world, having B blocks things that have P from having M. The possibility of such blockers is compatible with the thesis that any minimal physical duplicate of our world is a duplicate simpliciter of our world and, indeed, as well, with naturalism being true of our world. But it is claimed that it should be incompatible with physicalism.

There is no consensus in the literature about how, exactly, the possibility of blocker cases should be handled by physicalists or even whether physicalism should rule out all blocker cases. But one option is to maintain that physicalism is the thesis that everything in our world is either physical or metaphysically necessitated by the physical. (That doctrine faces the problem of a necessarily existing God, since such a God would trivially be necessitated by anything. But, again, that problem might be handled by also requiring for physicalism that naturalism be true.) That thesis is stronger than the thesis that any minimal physical duplicate of our world is a duplicate simpliciter of our world in that it implies that thesis but is not implied by it. Blocker cases do not arise for this stronger thesis since if it is true, then M (which by hypothesis is in our world) will be metaphysically necessitated by the physical, and so any physical duplicate of our world would include it, regardless of what else it included.

The thesis that everything in our world is either physical or necessitated by the physical may be too strong, however, to be required for physicalism. On the assumption that laws of nature are metaphysically contingent, for a physical property to metaphysically necessitate a functional property F, it will have to be a conjunctive physical property that includes as a conjunct not only a physical property that occupies the relevant functional role, but that also includes as conjuncts the physical laws in virtue of which the physical property plays the role. And even that may be insufficient to guarantee that the functional properties that physicalism should capture are metaphysically necessitated by physical properties. The conjunctive property may also have to include as a conjunct the property of being in a world such that any minimal physical duplicate of the world is a duplicate simpliciter of it, which is not a property that would be posited by the completed physics (McLaughlin, 2007).

Yet another strong formulation of physicalism concerns relationships between truths (or facts). Thus, physicalism is sometimes taken to be the thesis that all truths are physical truths or else hold in virtue of physical truths. This may seem too strong since, for instance, mathematical truths do not hold in virtue of physical truths. Indeed, given the extensive use of classical mathematics in physics, arguably, certain physical truths hold, in part at least, in virtue of certain truths of pure mathematics, namely the axioms of Zermelo–Fraenkel set

theory with the axiom of choice, which provide, in conjunction with classical logic, the foundations of the classical mathematics. The in virtue of or grounding claim could be weakened to the thesis that all contingent truths are physical truths or hold in virtue of physical truths. But then it would be compatible with the claim that there is a necessary God, something that would be necessarily true if it were true. Instead of so restricting it, however, it might be claimed that the truths that figure in the foundations of the mathematics deployed in physics should, because they so figure, count as physical truths.

Elimination or Location?

Although there is no consensus as to how, exactly, physicalism should be formulated, it is, as noted above, fairly widely held that physicalism requires that any minimal physical duplicate of our world is a duplicate simpliciter of our world. Even though that does not suffice for physicalism, it is a very strong requirement indeed. Let us call the thesis that any minimal physical duplicate of our world is a duplicate simpliciter of our world 'the physical minimality thesis'. Physicalists aim to defend the physical minimality thesis on empirical grounds and grounds of overall coherence and simplicity of total theory.

Consider the kinds of objects and properties posited by the various special sciences. Those kinds are typically ones that no recognizable descendant of current physics will explicitly posit as such. Given their commitment to the physical minimality thesis, physicalists thus incur the dialectical obligation of either defending an eliminativist position as concerns them (denying their existence Stich, 1999) or else justifying the claim that any minimal physical duplicate of our world will include those kinds and the exact same worldwide pattern of instantiation of them as in our world. Consider also that we ordinarily take there to be persons, beliefs, desires, intentions, emotions, aches, pains, itches, cities, countries, shopping malls, yard sales, wars, and morally right or morally wrong actions, just to name a few of the sorts of things that we ordinarily take there to be. As concerns each of these, the physicalists incurs the dialectical obligation of either defending an eliminativist position or else justifying the claim that any minimal physical duplicate of our world will include them and the exact same worldwide pattern of instantiation of them as in our world. Physicalists are typically (though not invariably) realists about such matters; they typically eschew eliminativism as concerns them. They aim to discharge the dialectical obligation of justifying the claim that any minimal physical duplicate of our world will include these things and have the same worldwide distribution of them as in our world. That is a truly formidable task.

A leading view is that discharging that dialectical obligation requires solving location problems (Jackson, 1998), problems of saying how the things in question, or at least things that metaphysically necessitate them, could, in principle at least, be located in the description that an ideally completed physics would provide of our world, on the assumption that that physics is a recognizable descendant of current physics. Thus, the location problem for an apparently nonphysical property is to see how it or a property that metaphysically necessitates it could be located in such a description. There are two basic strategies that typically get invoked here; which is invoked depends on the kind of apparently nonphysical property in question. (Analogous claims will be true for apparently nonphysical kinds of objects or stuff.) One strategy is to argue that a certain apparently nonphysical property is indeed nonphysical, but is a functional property that must exist and be instantiated, exactly as it is in our world, in any world that is a minimal physical duplicate of our world. The other strategy is to argue that the apparently nonphysical property is in fact a certain physical property, and so not in fact a nonphysical property. That strategy is typically implemented in either of two ways. Sometimes it is argued that there is a functional description that expresses a contingent, a priori reference fixing description for the relevant nonphysical term or concept that we use to denote the property, and that there is a recognizably physical property that meets that description, that is, that fills the functional role described (Jackson, 1998; Kim, 2005). This is a kind of filler (or realization) functionalist account of the property. Also, some physicalists argue that an apparent nonphysical property, for instance, a mental property M, is identical with a certain physical property P, but that the relevant identity claim is a posteriori and M as such bears no a priori link to physical or functional descriptions, and so admits of no functional analysis. Whether the location problems can be solved in all cases of in which eliminativism should be rejected is a highly controversial matter. (It should be mentioned here that physicalist theories of qualia (the what-it-is-like for the subject aspects of experience) often attempt to locate mental properties among physical properties very broadly construed (e.g., among neurobiological properties), rather than among properties of completed microphysics (Smart, 1959; Hill, 1991; Loar, 1997; McLaughlin, 2011). Such a view does not entail the general doctrine of physicalism. But whether qualia can be so located is also a very controversial matter.)

Nonphysicalists that embrace a kind of property dualism maintain that the location problem cannot be solved for certain properties (even if the physical is very broadly construed). For example, nonphysicalists typically argue that the location problem cannot be solved for qualia (Jackson, 1982; Chalmers, 1996; Kim, 2005). Indeed, some maintain that a minimal physical duplicate of our world would be, unlike our world, devoid of consciousness, and so be a world in which our physical duplicates lack any consciousness at all, and so are 'zombies' (Chalmers, 1996; Kirk, 2012).

It has also been argued that the location problem cannot be solved for intentional properties (e.g., being a belief that P) and/or for normative properties (those that fall on the ought side of the is/ought divide). Such property dualists maintain that a minimal physical duplicate of our world would differ from our world either in not including such properties or instantiations of them, and so that physicalism is false.

Suffice it to repeat that physicalism is a controversial doctrine. Its truth remains a matter of dispute.

Abstract

Passionately interested in biology and philosophy in his adolescence, Jean Piaget completed studies in natural sciences in his hometown (Neuchâtel, Switzerland). He then studied psychology and history of sciences in Zurich and Paris. From 1921, when he was appointed researcher at the J.-J. Rousseau Institute in Geneva, until his death in 1980, he conducted research in this institution, with the help of a team of coworkers. His early psychological research on the specificity of children's thought brought Piaget almost immediate international fame. In the 1930s he became professor at the University of Geneva and codirector of the J.-J. Rousseau Institute, and published books on infant cognition with an original model inspired by biology. The numerous books published in the following decades used a new formal model to explain children's (and later adolescents') reasoning abilities. Prodigiously productive, Piaget continued to research and write until the end of his life, studying various fields beside psychology and epistemology and developing constantly new concepts to explain cognitive development. His comprehensive 'constructivist' theory, based on innumerable experimental data, had a considerable influence on child psychology and on the development of cognitive developmental psychology. By its multidisciplinary approach it is a precursor of today's cognitive science.

A most productive scholar in the area of children's intellectual development, Jean Piaget was primarily interested in epistemology or theory of knowledge. His genetic psychology (psychology of the genesis of thought) was intended to provide a scientific basis for epistemology, with the main concern to explain how knowledge can become more rigorous and more objective. Piaget's psychological explanations were inspired by several scientific disciplines and beside his studies in psychology and epistemology he published in other fields such as biology, logic, and sociology. His work derived from evolutionist approaches rooted in the nineteenth century yet it is still in line with scientific trends at the end of the twentieth century.

The core of Piaget's theory is the conception of mind as an active system that, like an organism, assimilates external data into its structures and can adjust to these data. Special emphasis, in the knowledge process, is placed on the subject's activity and the structures through which he or she perceives and understands things. Thus, the development of knowledge is viewed as the construction of new structures (rather than the accumulation of new information) triggered and guided by internal processes during the subject's encounter with reality. Each new stage in this process opens up new possibilities. In this interactionist conception, structures are neither predetermined nor found in the environment and there are striking similarities between biological evolution, cognitive development in children, and the development of scientific thought.

Seven Decades of Scientific Productivity

Childhood and Adolescence (1896–1918)

Jean Piaget was born in Neuchâtel, a small city of Switzerland, on 9 August 1896. He was the son of an historian and professor of medieval literature at the university. Of his mother, he wrote in his autobiography that she was an intelligent and energetic woman, whose psychological imbalance created problems in the family. At the age of 11 years, Jean Piaget started classifying and collecting mollusks with the help of the director of the natural history museum of his hometown. In his teens, he was already an acknowledged specialist in the field and started publishing papers in scientific journals (as of 1911). This activity led him to decide to study natural sciences at the university between 1915 and 1918. At the same time, as of the age of 16 he became passionately interested in philosophy, and particularly in the theory of knowledge or epistemology. He soon decided to devote his life to the elaboration of a biological theory of knowledge, whose goal would be to explain the evolution of ideas both in individuals and in the scientific community. This project was influenced by evolutionary approaches in the field of biology (Lamarck, Darwin) and in philosophical works on issues of intelligence (Spencer, Le Dantec, Bergson). In the following years, Piaget's professor of philosophy A. Reymond convinced him of the importance of a rationalist approach making use of logic and mathematics.

In 1918 Piaget published a philosophical and autobiographical novel (*Recherche*) describing the crisis he had gone through because of the conflict he felt between religion and science, or, in other words, between value and rationality. Eventually, the search for truth, which is the goal of science, became the most important value for Piaget. *Recherche* also contained the outline of a theory of the evolution of living and cognitive organizations based on the idea of improving forms of equilibrium between the whole and its parts. Piaget's twofold interest on the one hand in biology and the associated problems of the organization and evolution of living beings, and on the other hand in epistemology and related issues concerning the validity of knowledge and its development, forms the basis of all his work.

Complementary Studies (1918–21)

Piaget was convinced that a theory of knowledge should be validated by psychological research, and decided to get training in scientific psychology as soon as he graduated from

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61107-8

university with his PhD thesis on mollusks in 1918. He then spent a term in Zurich, attending courses in psychopathology – where he encountered psychoanalysis – and in experimental psychology. He then studied in Paris from 1919 to 1921, where he attended lectures in psychology (specifically by Janet), philosophy (with Lalande), and history of science (by Brunschvicg who had great influence on Piaget's ideas). Courses in psychopathology provided him with a clinical interview method, which he soon used in his discussions with children. In effect, in parallel with his studies, he worked in the laboratory of Binet and Simon, standardizing intelligence tests for children. Piaget was fascinated by the reasoning of the children who did not yet answer 'correctly,' and he discovered that the study of children's thinking could be a means to validate a theory of knowledge. This program, which was to be the main focus of his work for 60 years, was very similar to the program designed by James Mark Baldwin (1861–1934), from whom Piaget borrowed several concepts and the expression 'genetic psychology.'

The Early Psychological Research (1921–29)

In 1921, Claparede offered a position in his Institute for educational sciences (known as the Jean-Jacques Rousseau Institute) in Geneva to Piaget, who was to conduct most of his professional life in this institution. What he found there were stimulating intellectual atmosphere and students willing to assist him in his work. Together with them the young researcher started a series of studies of children's reasoning and soon published his first books: *The Language and Thought of the Child* (1923); *Judgment and Reasoning* (1924); *The Child's Conception of the World* (1926); *The Child's Conception of Physical Causality* (1927) (the titles given here and in the remainder of this text are the English translations of the French originals; the years are those of the original publications). The striking facts he discovered about the use of language, the nondifferentiation of concepts and the explanations of physical phenomena in children, as well as the detailed analyses and the synthetic categorization of these behaviors, brought Piaget almost immediate international fame. These studies showed that young children's thinking is structurally and functionally different from that of older children and adults. Young children lack a true logic of classes and relations, they have difficulties viewing reality from an objective viewpoint, and they lack moral norms, which command compliance on the basis of a feeling of necessity. Children's thinking tends to be egocentric, that is, they have difficulties in looking at things in perspective. In these early works, the passage from egocentric thought to a logical and more objective form of thinking was explained by a social factor: cooperation, or exchange between individuals who consider themselves as equals.

During this period, Piaget was involved in many activities beside his research. He taught child psychology at the J.-J. Rousseau Institute, philosophy and history of science at the University of Neuchâtel (1925–29), was for a few months psychoanalyzed by Sabina Spielrein, a pupil of Freud, and continued to study the evolution of mollusks. In 1923 he married a student at the Geneva Institute. Piaget and his wife Valentine spent much time minutely observing their three children who were born between 1925 and 1931. These observations were the basis of several books published in the following years.

Administrative Responsibilities, Professorship and New Directions of Research (the 1930s)

In 1929, Piaget was appointed professor of history of science at the University of Geneva, where he subsequently became professor of sociology (1939) and of experimental psychology (after the death of Claparede, 1940). He also played an important administrative role at the J.-J. Rousseau Institute as associate director (1929), then as codirector (since 1932), reorganizing the Institute and establishing links between the Institute and the University. At the same time, and until the 1960s, he was director of the *Bureau International de l'education* and managed to convince the governments of many countries to join that organization.

Piaget's most important activities continued to be research and writing. During these years, he accumulated data on children's reasoning. However, apart from his book on moral judgment (1932) – simultaneously in French and in English – which was the sequel to the psychology books published in the 1920s, his major publications dealt with infant cognitive development. The choice of this topic stemmed from Piaget's conviction that logic has its roots in actions and also from his deep interest in the issue of the origins of knowledge. *The Origins of Intelligence* (1936) and *The Child's Construction of Reality* (1937) contained extremely original observations and explanations of infant behaviors, and departed radically from Piaget's earlier writings as far as the explanatory model was concerned. Piaget discovered behaviors that had previously been overlooked, for example, the failure of babies younger than 9 months of age to look for an object hidden in front of them. Replications of these observations and experiments many years later around the world have confirmed these findings that had resulted from the observation of his three children.

In view of theory building, Piaget analyzed the elements of knowledge, the 'schemes' of actions, which become more differentiated and coordinated as development progresses. They evolve into increasingly complex and better-adapted forms of behavior, from automatic 'reflexes' to intelligent activities. This development is a special case of the relationship between the organism and the environment, in other words of biological adaptation. It results from the interaction between the subject of knowledge, who assimilates reality to his or her structures, and the object of knowledge, which may elicit an accommodation of these structures. Cognitive development is viewed as an evolving equilibrium between assimilation and accommodation. In *The Child's Construction of Reality* (1937), Piaget studied the growth of the practical knowledge of object permanence, space, time, and causality in infants. He introduced a new and abstract explanatory notion: the mathematical concept of 'group,' which several authors in the social sciences considered as an interesting model at the time. Piaget applied it to the organization of spatial knowledge in infants and was convinced that it could be used to explain the logic of school-age children. To this end, from 1937 onwards, he worked for 3 years on this model, expressing it in algebraic formulae.

Although Piaget was now a famous author who had received an honorary degree from Harvard University in 1936, his two books on infant cognition were not translated in English until the 1950s. They contained too many abstract considerations and microanalyses and were definitely ahead of their time. A third book, also based on the observation of Piaget's own children, was written during this period and published later: *Play, Dream and Imitation* (1945). It dealt with imitation in infants and the origins of symbolic thought in young children. Intellectual activity as well as play and imitation were defined in terms of equilibrium or disequilibrium between assimilation and accommodation.

The Mature Years: The Advent of Structural Analysis (1940s)

During this and the following period, Jean Piaget was prodigiously productive, thanks to a strict and very regular work regime. In the mornings he would teach, discuss research with his large team of coworkers, and perform his administrative duties. Piaget would then spend the rest of the day mostly by himself. In the early afternoon, while thinking about the topics of his current writing, he would stroll or ride a bicycle in the countryside near Geneva. During the rest of the afternoon he would write, which was the best way for him to elaborate his ideas. Even when traveling or attending conferences he would not let a day go by without writing a few pages. Although he loved classical music he almost never went out in the evenings to movies, theaters or concerts. Both in summer and in winter, his love of nature led him to repeated sojourns in the mountains of the Valais, where he both hiked and worked.

The logical model of 'grouping' of mental operations, which he had recently developed, and which accounted for the organization of inferences in overall structures, inspired much research and writing. It permitted Piaget not only to describe the limitations of young children's reasoning as he had done in his first books, but also to explain the sudden, stable, and rather generalized intellectual progress due to the advent of the elementary logic, of 'concrete operations.' Between 1941 and 1948, his work resulted in six books: *The Child's Construction of Quantities* (with B. Inhelder, 1941), *The Child's Conception of Number* (with A. Szeminska, 1941), *The Child's Conception of Time* (1946), *The Child's Conception of Movement and Speed* (1946), *The Child's Conception of Geometry* (with B. Inhelder and A. Szeminska, 1948), *The Child's Conception of Space* (with B. Inhelder, 1948). These books study the elementary mastery of basic scientific concepts. This mastery, which usually emerges between the ages of 6 and 8 or 9 years, was explained in terms of the underlying 'grouping' structures that organize mental operations. This type of structure entails the reversibility of thinking, for Piaget an essential feature of natural logic. In contrast, younger children think that the number of a set of objects or the quantity of a substance change when spatial transformations occur, and that the duration of a movement corresponds to the distance covered, without taking into account the relative speed of the moving objects. These young children have difficulties comparing the number of elements in a subclass with the number in the superordinate class. As to space, geometrical capacities like inverting a spatial order, constructing a straight line with vertical sticks using a sighting method, and drawing the horizontal line of the water level in a tilted glass also usually emerge after the age of 7 years. The basic concept studied in each book was analyzed and defined in the light of children's answers. For example, number was analyzed in terms of a synthesis between logical classification (class inclusion) and the seriation of asymmetrical relations (ordering by increasing or decreasing size); time was defined as the coordination of movements, in which the ability to consider speed played a fundamental role, and so forth.

Piaget also published a *Treaty of Logic* (1949) and with his coworkers he studied perception in children in the laboratory of experimental psychology. These studies, which attracted Piaget's attention to the phenomenon of regulation, were to provide the subject matter of a much later book. The same holds true for the papers in sociology which were published during this decade and collected in a book called *Sociological Studies* in 1965.

The second World War rendered contact with foreign colleagues difficult, but Piaget was invited in 1942 to give a series of lectures in Paris at the '*College de France*' (published in *The Psychology of Intelligence*, 1946). The abstract nature of his explanations struck many listeners as much as the brilliant analyses inspired by various scientific disciplines. After the war, UNESCO entrusted Piaget with several missions.

Achieving the Ultimate Goal of His Work: The Elaboration of a Genetic Epistemology (1950s)

In the 1950s, while continuing his work in genetic psychology with the help of his coworkers, Piaget devoted much of his effort to the foundation of a genetic epistemology, i.e., the study of the basic concepts and processes of the development of scientific knowledge. This used to be a topic of philosophical study but now became an object of scientific analysis. Actually, Piaget had indeed pursued epistemological issues throughout his entire previous work while ostentatiously focusing on the explanation of children's thinking. Now he wished to discuss questions of knowledge per se as they were raised in the sciences (but continued to use the study of children's cognitive development for this purpose). In 1950, Piaget published three volumes of an *Introduction to Genetic Epistemology*. The book begins with a general introduction defining genetic epistemology and its method and stating the main issues. Piaget develops an idea he had already expressed in earlier writings, that of a 'circle of sciences': physical reality is explained by mathematics, mathematics is the product of mind, which is a result of biological evolution, and organisms are closely connected with physical reality. The book deals in great detail with the epistemology of mathematics and physics, and in lesser detail with the epistemology of biology and the social sciences.

To make progress in the domain of genetic epistemology, Piaget founded the International Center for Genetic Epistemology, which was a working group comprising researchers in psychology and scientists from various disciplines (mathematics, physics, logic, etc.). The Center was launched in 1955 after obtaining, with difficulty, the necessary funding. A new series of books, which contained the results of the studies conducted at the Center for genetic epistemology, appeared from 1957 onwards. About 40 volumes were published in the series until the death of Piaget in 1980.

During the 1950s, when Piaget held a position as professor at the University of Paris (1952–63), his psychological research in Geneva continued to progress and resulted in three books with B. Inhelder: *The Development of Elementary Logical Structures* (1959), a sequel to the studies of concrete operations; *The Origin of the Idea of Chance* (1951) and *The Growth of Logical Thinking from Childhood to Adolescence* (1955). The latter book provided a new description and definition of the highest stage of logical development: the formal operational stage achieved between the ages of 12 and 15 years. The formal model of the INRC group, derived from Klein's mathematical group, provided an account of the new possibilities of reasoning which were available to adolescents. It involved a greater number of combinations of operations than the grouping structures (in particular a 'double reversibility' of thought). Moreover, the experiments by Inhelder showed how the understanding of physical phenomena developed in children and how, through the use of an adequate interview procedure, adolescents could rediscover fundamental scientific laws on their own.

The Last Two Decades (1960 to 1980): The Pinnacle of Fame

Only in the late 1950s was Piaget's work rediscovered by English and American psychologists, although he already had been a most respected professor and researcher in the French-speaking countries, and a well-known author in many other countries. During the following two decades he was among the most cited psychologists and best known scientists in the world. Most of his books were translated from French into foreign languages (a total of 24 different languages). From the end of the 1950s onwards, he received an increasing number of honorary degrees each year. When he died, he had received over 30 honorary degrees and several prestigious awards. However, these honors and the travels they involved did not prevent Piaget from continuing his work.

Until the beginning of the 1970s, studies of genetic epistemology mainly focused on problems related to logic, language, space, time, and causality. The latter topic – strangely neglected for several decades – proved difficult to study and remained on the program of the Center for Genetic Epistemology for several years in succession. On the whole, these books, while discussing issues specific to each science (e.g., the relative importance of time and speed in judgments about duration, or the possibility of geometrical intuition) validated the constructivist conception of Piaget's epistemology. Effective forms of knowledge are neither innate nor drawn from the observation of the environment. They derive from the interaction of active individuals with their environment. A consequence of this position (summarized in the short book *Genetic Epistemology*, 1970a) is that the rate of intellectual development can be only moderately accelerated by education. The goal of education, according to the few texts devoted by Piaget to this topic (for example a long article in 1965) is to favor children's intellectual activity and their discovery ofrelationships and abstract concepts.

During the 1960s Piaget returned to his earliest field of interest: biology. He published a paper on the evolution of mollusks and about the reproduction of the 'sedum' plants, which he grew in his garden and observed carefully. In his book *Biology and Knowledge* (1967) he developed his ideas on biology and the parallel between biological and cognitive development. Simultaneously, he published three books on psychology. They dealt with the 'figurative' aspects of knowledge, whose function is to provide a kind of copy of things: *The Mechanisms of Perception* (1961), *The Child's Mental Imagery* (1966), and *Memory and Intelligence* (1968). These books showed that figurative aspects are progressively subordinated to the subject's operations: some optical illusions decrease with perceptual activity, and with the advent of logical thinking (concrete operations), mental images can adequately represent transformations, while memory of organized material improves. Intelligence is not captured by representation, i.e., a system of images or linguistic symbols; rather intelligence consists in operating on elements of reality or symbols and thus transforming them.

In the 1970s, after Piaget's retirement as professor at the University of Geneva (1971), he continued his work with a large team of researchers at the Center for Genetic Epistemology. Most of his publications dealt with processes of cognitive development. For over 20 years, his main aim had been to demonstrate that efficient forms of knowledge result from structures that organize mental operations, and that these structures, which become increasingly complex over time, are rooted in biological organization. The time had come to deal with the processes involved in the construction of these structures, a topic that Piaget had neglected since the 1930s, except for a few epistemological papers written in the 1950s. During the last decade of his life, between the ages of 75 and 84 years, Piaget developed concepts that had been introduced earlier but needed fuller consideration and a precise definition: equilibration, reflexive abstraction, generalization, the opening up of new possibilities, and so on. These concepts are highly interesting and very original ideas, difficult to operationalize, but with deep and general explanatory value. Unfortunately, Piaget was so eager to continue his work that he changed the focus of his research and his writing nearly every year, although these complex concepts would deserve more sustained treatment.

Reflexive abstraction is the process through which something new is abstracted from experience. What is abstracted is not a property of the external world, but derives from the organization of the subject's actions or operations. Equilibration is a self-regulation process, which is specific to living organizations. At the cognitive level, it is a reaction to an intellectual perturbation (such as a contradiction) which regulates the cognitive system and, in an attempt to compensate the perturbation, creates improved forms of knowledge. For his eightieth birthday in 1976, a kind of dissertation defense was organized: Piaget defended the theses developed in *The Equilibration of Cognitive Structures* (1975) before a 'jury' composed of famous scientists who represented different disciplines. In this last period, Piaget's work also dealt with the grasp of consciousness, contradiction, and dialectics. He explored the relevance to the explanation of cognition of the mathematical concept of morphism and of the idea of logic of meaning. The last work was conducted in collaboration with R. Garcia who was also coauthor of *Psychogenesis and History of Science* (published posthumously in 1983). Piaget also dealt with problems of biology. His post-Lamarckian

ideas attributed some importance to aspects of experience in the evolution of species (for example in *Behavior, a Motor of Evolution*, 1976).

Factors of Scientific Creativity

Piaget died on 16 September 1980, leaving behind a life's work of unusual scope, in terms of depth, originality, interdisciplinary relevance, and volume. The explanation of his exceptional scientific productivity is not only the conjunction of a brilliant mind with a great capacity for work, but also the stimulation of reflection by the results of constantly renewed research. It was also due to Piaget's sociability, which enabled him to easily convince others to work with him; and to a strong sense of a mission to which everything else was subordinate. According to Piaget, having a theory to contradict was a powerful stimulus. The dominant empiricist conceptions in psychology – neoassociationism – and logical positivism in philosophy played this role well into the 1960s. Since the mid-1960s, Piaget was busy developing arguments against the relatively widespread idea, prevalent since Chomsky published his work, that important aspects of knowledge are innate.

The Importance of Piaget's Work for the Social Sciences

Piaget's theory is exceptionally comprehensive, as it gives a detailed account of cognition from birth to adolescence, and also deals with scientific knowledge in adults. It contains an incredible wealth of experimental data covering these periods in life, especially the age range from 5 to 9 years. It deals with fundamental problems often ignored in other psychological theories, such as the relationship between biological activity and cognition, the relative role of the subject and the environment, and the connections between different aspects of cognition such as perception, reasoning, and memory. In some respects Piaget's work was ahead of its time and it could therefore easily establish connections with emerging disciplines such as cybernetics (since the mid-1940s) and, later, artificial intelligence. The concepts of self-regulated systems and of feedback specific to cybernetics were involved, less explicitly, in the Piagetian ideas of reversible structures (present in his work at least since 1937) and of the regulation of cognitive activities (frequently referred to by him in the early 1940s). The artificial intelligence programs which expressed in symbolic language the expertise involved in the mastery of a task bear some resemblance to the Piagetian concept of repeatable action schemes and recall Piaget's attempts to formalize mental structures. Moreover, the multidisciplinary approach known as cognitive science, which emerged in the 1980s, is completely in line with Piaget's approach, with its links between biology, psychology, logic, and physics.

One aspect of Piaget's work, genetic epistemology, which is focused on scientific knowledge as investigated through studies of children, has had little impact outside of Geneva. By contrast, Piaget's psychological work has definitely influenced subsequent orientations and research in the social sciences.

Since the 1920s, Piaget's findings about the reasoning of children had considerable influence on child psychology. The influence was strong in the 1960 and 1970s, in particular regarding the four successive stages of cognitive development, (sensorimotor, preoperational, concrete operational, and formal operational). In fact, Piaget's idea was not to define general stages of child development, but necessary steps in the integration of new forms of knowledge. His detailed findings concerning the emergence of new capacities, such as the search for hidden objects in babies, conservation of quantity in school-age children, and combinatory operations in adolescents remain useful landmarks of psychological development although they cannot be used as psychometric tests. During the same two decades, various experiments in education were directly inspired by aspects of the theory, namely the role of the child's activity and the importance attributed to general structuring abilities rather than specific learning. However, mainstream psychology and education, especially in English-speaking countries, often remained impervious to Piaget's influence, except for the growth of cognitive developmental psychology.

Cognitive developmental psychology became a productive subdiscipline of psychology, especially since the beginning of the 1970s. Practically every developmental psychologist in the world at that time had at least some knowledge of Piaget's work and the very idea of studying cognitive development using a cross-sectional method was inspired by the work previously undertaken in Geneva. Piaget's writing often played the same role of a 'theory to contradict' that associationism or nativist conceptions had played for Piaget. Many authors in developmental psychology launched their careers by conducting experiments that were designed to prove Piaget wrong. Because his constructivist conceptions grant a limited role to social influence, and in particular to education, they were unacceptable to many. Much research has been performed especially in the USA to show that cognitive competencies existed in children well before the ages indicated by Piaget. In order to demonstrate this, the problems presented to the children were modified and compared to those presented by Piaget himself. The race for early competencies in the 1980 and 1990s gave rise to the idea that many cognitive capacities were innate. In the end, Piaget's conceptions were not followed, but thanks to his work a whole field of psychology developed.

Piaget's work paved the way for the cognitivist revolution in psychology, from the mid-1960s onwards. Psychologists had become interested in mental states, a taboo for many decades due to the predominant behaviorist conception. The new generation of psychologists could read in Piaget's work detailed studies of mental states that had been conducted over a period of several decades.

At the end of the twentieth century, Piaget's theory had indirect descendants in the fields of child psychology, cognitive science, and developmental psychology. Ideas of specialists in educational science are more directly inspired by Piaget's work, especially in French-speaking countries and in Latin America. Studies in moral development also derive directly from Piaget's research in this field. More generally, constructivist approaches which attribute importance to the activity of the subject, in applied psychology as well as in other disciplines, usually refer, albeit vaguely at times, to the work of the Swiss psychologist and epistemologist.

Piaget's Theory of Cognitive Development

Anik de Ribaupierre, University of Geneva, Genève, Switzerland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Piaget's theory is one of the major and enduring contributions of the twentieth century to developmental psychology and education, and is firmly grounded in biology and epistemology. This article first reviews some key epistemological concepts, since Piaget's project was epistemological before being psychological. It then briefly summarizes Piaget's theory of the development of intelligence (stages and factors of development). A few major criticisms brought by developmental psychologists are reported, and the major legacy of Piaget's theory is summarized. Present and future directions of research are finally reviewed.

Introduction

It might seem a little bit strange to offer in 2014 an update of a notice on Piaget's theory. By very definition, the notice will adopt a historical connotation; after all no revision to the theory itself has been introduced. Yet, Piaget's theory has been and still is so influential that it has to be included in the revision of the encyclopedia. Moreover, it remains a surprisingly modern theory in view of the later advances in developmental psychology. The update of the notice will evidently concern more closely studies inspired by the Piagetian theory, while the summary of the theory itself will lean very heavily on the notice published in the first edition of this encyclopedia.

Jean Piaget (1896–1980) has been qualified as one of the two giants of psychology of the twentieth century (e.g., Papert, 1999; see also Hopkins, 2011). His theory counts as one of the most influential and enduring theories of cognitive development, and is firmly grounded in biology and epistemology. Although the focus of this article is on the cognitive developmental aspect of his work, it will first review some of the key epistemological concepts that Piaget adopted (such as constructivism, adaptation, equilibration, abstraction), because genetic epistemology and genetic psychology were closely interrelated. Piaget's theory of the development of intelligence (stages and factors of development) will be briefly summarized. After having mentioned a few major criticisms raised in developmental psychology, the major legacy of Piaget's theory is summarized. Unsolved issues as well as some fundamental misunderstandings of the theory by developmental psychologists are discussed. Present and future directions of research are finally reviewed.

The Epistemology of Piaget

Piaget, who trained as a biologist, had as main objective to understand the development of knowledge in the human species, and particularly the development of the scientific and logical thinking; it was not to offer a psychological theory of how children develop. His first originality was to address philosophical questions (such as the origin or the development of knowledge) by empirical means, in particular by relying on the study of child development (supposed to be, at the beginning of his career, a mere 'detour' of some years). He established the discipline of genetic epistemology (the term 'genetic' referring to the concept of genesis or evolution, as proposed by Baldwin), with the aim "to study the roots of the various sorts of knowledge from their most elementary forms on and to follow their development in ulterior levels including scientific thinking," and by grounding it in both historicocritical and psychogenetic approaches. Piaget's epistemology is constructivist, in the sense that knowledge is neither a mere reflection of the external world (realism) nor a projection of preexisting structures of the mind (nativism); it is to be actively constructed; the origins of knowledge are to be found in the practical and cognitive activity of the subject. Piaget's epistemology is also fundamentally interdisciplinary. Note in passing that he created in 1955, with the support of the Rockefeller Foundation, a very successful interdisciplinary center, the Center of Genetic Epistemology, which attracted numerous scientists from the entire world. Many of the ingenious experimental situations were proposed in that interdisciplinary group.

Piaget's primary hypothesis was that intelligence is a form of biological adaptation (e.g., Piaget, 1967), that is, intellectual or cognitive behaviors are the products of an organism, in interaction with its environment, and the end point of biological evolution. This is not to say that psychological phenomena can be reduced to biological ones. Piaget always opposed biological reductionism; intelligence is an organizing activity whose functioning transcends biological organization, by elaborating new structures. The main characteristic common to knowledge and to living organisms is their adaptive character. Adaptation itself, whether biological or cognitive, relies on two mechanisms, defined very early in Piaget's work, namely, assimilation (incorporation of new information into an existing system – see also Baldwin) and accommodation (modification of existing schemes or structures by newly assimilated elements, so as to respond to the demands of the environment). By so doing, actions and operations become coordinated with one another; such coordinations define a new entity, which in turn constitutes a new object for thought and action. This is the process that Piaget labeled equilibration. Contrarily to frequent but too simplistic interpretations, equilibration does not correspond to a stable (even if only temporary) state of equilibrium, but is the process of coordination in itself.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23093-6

As a consequence of the functional continuity that Piaget postulated between biological and psychological entities, a given level of knowledge is always considered to result from a reorganization of the preceding one. Reconstruction not only means more than a mere addition of elements of a lower type in order to attain a higher level, but also implies a total reorganization and a change in scale. One direct consequence of a constructivist perspective is that an epistemologist or a psychologist studying any level of development will ask what characterized the previous level and will stress developmental progression toward higher levels. Piaget always declared that the functioning of a given cognitive system cannot be understood without also understanding how it developed. An essential mechanism for this reconstruction is reflecting or reflexive abstraction, that is, a process by which the subject extracts characteristics or coordinations from actions or operations; it is called 'reflecting' both because it consists of a mental reorganization and because it implies a reflection in a physical sense, or a transfer onto a higher level of what was established at a lower level. Reflecting abstraction is contrasted with empirical or simple abstraction, which bears mainly on observable characteristics of objects or classes of objects.

The Psychology of Jean Piaget

Piaget's psychology of intelligence is the most universally known part of his work, even though he himself did not consider it as the major part (e.g., Piaget, 1947, 1970; Piaget and Inhelder, 1966a). His theory transformed the field of developmental psychology by providing it with a new vision of the development of the child, to the extent that almost every developmental study has some connection with a question Piaget raised. Intelligence is defined as the most general form of coordination of the actions and operations that characterize the various developmental levels, and not as a mental faculty or an entity in itself; it develops through a succession of general stages, defined by overall structures (*structures d'ensemble*). Piaget was, once again, not interested in individual or task-specific performances, but in the generic behavior of subjects in classes of situations; this is what he called the *epistemic subject*.

The successive stages or levels are general structures, which appear in a fixed order of succession, but are not necessarily tied to a given age, and which are such that a given structure n integrates, as a substructure, the preceding structure $n-1$. The number of stages defined in Piaget's publications varied from three to five. Most often, he referred to four stages: (1) the sensorimotor stage (approximately the first 2 years), itself consisting of six substages, or three periods. This stage is characterized by the development of practical schemes, among which is the scheme of object permanence (operationalized by the study of the search for hidden objects), one of the most studied domains in modern infancy research; (2) the preoperational stage from approximately 2–6 years of age, also labeled representative (prerelational and intuitive, or prelogical) period, made possible by the emergence and the development of the symbolic function; (3) the concrete operational stage (7–12 years) during which invariants (conservation), logical classes and relations, the concept of number, as well as different concepts of space develop, all of which are marked by reversibility; and (4) the formal operational stage, during which adolescents develop hypotheticodeductive reasoning (i.e., beyond concrete objects and actions) and experimental schemata. Piaget used abstract algebra to formalize the underlying structures: a group of displacements for the sensorimotor stage, groupings for the concrete operational stage, and a group of four operations (Identity, Negation, Reciprocal, Correlative (INRC) group) for the formal operational stage. He also attempted to formalize the preoperational stage by means of the logic of functions, but this effort was not pursued. Other cognitive activities such as mental imagery, perception, memory, and language were always dealt with by Piaget in relation to the development of operational structures. They were termed 'figurative' because they attempt to represent reality as it appears. Figurative activities are contrasted with (and subordinated to) 'operative' activities that attempt to transform reality (e.g., Piaget and Inhelder, 1966b).

Although Piaget grew less and less interested in the description of these general stages, this is probably the feature of his theory that was most often retained and criticized. In particular, the generality of the stages was questioned by the existence of *decalages*, that is, temporal lags between acquisition of concepts supposed to pertain to the same level. Readers of Piaget have often overestimated the necessity of synchronism in acquisitions across situations as implied by the theory. It should be stressed that Piaget did not postulate that the generality of structures meant strict synchronism, even though some of his writings were admittedly ambiguous with respect to this issue (e.g., Chapman, 1988; de Ribaupierre, 1993).

Factors of Development

Piaget described four factors of development: (1) organic growth, and maturation of the nervous and endocrine systems; (2) experience, which Piaget further decomposed into a factor of physical experience (actions exerted upon objects in order to extract their properties by simple abstraction) and a factor of logicomathematical experience (extraction of knowledge by reflecting upon one's own actions, whether effective or mental); (3) social interactions and transmission; and (4) equilibration. This last factor was undoubtedly the most important for Piaget; he often paid little more than lip-service to the first three factors, whereas he spent considerable time in demonstrating the necessity of equilibration, which he considered to account for the 'vection' or direction of development (Piaget, 1975). Majoring equilibration (*équilibration majorante*) is seen as the causal mechanism underlying the progression of cognitive development. It is a dynamic sequence of states of disequilibrium–equilibrium and embodies the organism's strive toward a more general equilibrium. Equilibration is the only mechanism that, according to Piaget, can account for the emergence of novel behavior, even though more recent work has disputed the idea that Piaget's theory can really account for the emergence of novel behaviors. Cognitive structures are put into disequilibrium by perturbations that resist the assimilatory process and lead to errors or failures of action. Reequilibration is made possible by regulations, which entail the modification of an action as a function of

feedback regarding its previous outcomes, ultimately leading to compensatory reconstructions. Equilibration is thus necessary when contradictions and cognitive conflicts arise, hence the importance given by Piaget to cognitive conflict as a source of cognitive development.

Unsolved Issues in the Piagetian Theory

Piagetian theory has been subjected to numerous criticisms (perhaps proportional to his production) on the part of developmental psychologists, only some of which are summarized here. Most critics should be placed in the context of what Piaget's work was used for by other researchers (psychologists, educators, etc.), rather than directed toward Piaget's project. As mentioned above, Piaget's project was epistemological more than psychological, while most critics addressed the developmental theory of the child. First, numerous decalages, which could not be predicted by the theory, have been observed between concepts supposed to belong to the same structural level; between-task correlations are relatively low, implying that all tasks do not measure the same construct. This led a number of researchers to refute the general character of cognitive development; instead, they claim that development is domain specific. Moreover, the concept of overall logicomathematical structure proved very difficult to operationalize. Second, Piaget's portrait of the child appeared too universal and focused on the subject independently of his/her cultural environment; the biological origins of development were also felt to be too much emphasized. Third, the theory placed too much emphasis on the development of logicomathematical thinking, as contrasted with other forms of thinking. Fourth, Piagetian theory did not provide sufficient information on learning mechanisms and on the effects of training. Consistent with his epistemological project, Piaget was indeed interested in demonstrating the commonalities, in terms of general mechanisms, between learning and development rather than in focusing on the specificities of learning. Linked to this is the difficulty for the Piagetian theory to account for the appearance of novel behaviors. This is not to say that later theories have a better account for the emergence of novelty. Finally, like many other, general psychological theories, Piaget did not take into consideration individual differences; however, it has been shown that the variability in performance, whether intra- or interindividual, is much larger than could at first be suspected and constitutes a fundamental phenomenon rather than mere noise (e.g., de Ribaupierre, 1993; de Ribaupierre and Rieben, 1995).

As an illustration, Hopkins (2011) enumerates three criticisms of the Piagetian theory in the context of the early twenty-first century: (1) Piaget never gave any details about his samples, and provided almost no statistics while sometimes using very few participants; (2) Piagetian stages are too general, whereas present-day developmental theories consider the mind to be modular; (3) Piaget considered a too early age as the end of development (12–15 years of age), and did not consider that major change could take place in late adolescence or adulthood. Once again, these criticisms concern the psychological or educational use that can be made of the Piagetian theory, rather than the epistemological framework. Piaget was indeed not interested in statistics; the most advanced statistics that he provided was descriptive, such as percentages of response categories like in the book *Early Growth of Logic in the Child* (Piaget and Inhelder, 1959/1964). It was sufficient, from the perspective of his epistemological project, to empirically demonstrate the existence of a developmental sequence; it was not necessary to assess whether all children followed the same sequence. Obviously, however, from the standpoint of a psychological theory of development, it is crucial to determine whether all children develop in the same way, and at approximately what age.

The Heritage of Piaget

Despite the criticisms addressed to the theory, Piaget's theory leaves an enormous heritage, some of which is no longer even acknowledged, simply because it has been fully integrated into developmental psychology and education. First, the constructivist view of development that Piaget defended is presently widely held by cognitive developmentalists, as well as by educational and cognitive psychologists. Likewise, the concepts of assimilation and accommodation, even though probably too general, are adopted by a large number of theoreticians. The view of children construed as active thinkers has also been generally endorsed. Second, although there was a period in the 1960s and 1970s during which a large number of developmental researchers argued for domain specificity in development and against the existence of general stages, there is a growing consensus that the characterization of human cognitive development needs something more general than a long list of specific concepts, even if less general than the cognitive structures defined by Piaget. In any case, most developmentalists see the need for structural analyses that transcend any particular cognitive task. Similarly, the concept of scheme (defined as an invariant abstracted across several actions, to which new actions or objects can be assimilated and which allows for generalizations) has been retained and is close to other concepts such as schemas or scripts proposed in cognitive psychology. Third, although the construct of equilibration has been criticized for being too fuzzy, similar conceptualizations have been proposed, whether by dynamic systems theoreticians, or by neo-Piagetians.

Last, but not least, Piaget contributed enormously to the research methods used in developmental psychology, even though he was criticized for not using a standard, quantifiable methodology. He pioneered the use of a clinical method (later to be called critical method), in which the researcher probes for the child's understanding through repeated questioning. Piaget insisted that the child's incorrect responses reflect a complex, underlying cognitive system, and should not be merely recorded as failures. Also, Piaget's work was and still is a source of very ingenious empirical techniques, in many different fields; Piagetian measures such as conservation, class inclusion, spatial representation, perspective taking, object permanence, moral judgment, transitive inference, and many others have each produced countless studies by researchers around the world. Most of these tasks were very productive, because they

generated data that were both counterintuitive and generative of hypotheses about the way children think.

Bond and Tryphon (2007) examined the 1998 edition of the *Handbook of Child Psychology*, one of the most authoritative books in developmental psychology, to assess the impact of Piaget's theory, and compared it with the 1983 edition. Their analysis shows clearly that, as mentioned above, only a restricted period and, more importantly, a restricted set of Piaget's enormous production was retained. Although the number of references shows Piaget to be the most cited author in the field, citations are essentially restricted to his books, particularly those published between 1930 and 1975; most articles (the paper lists 523 articles written) are ignored, except the article that Piaget wrote on his own theory for the 1970 edition of that handbook (chapter reprinted in the 1983 edition). Also, the books most frequently cited are those on the sensorimotor period, on the one hand, and those dealing with the psychological development of the child. As mentioned above, Piaget's epistemological perspective was largely ignored, at least in the Anglophone world, despite the translations and the major importance that Piaget himself granted to this facet of his contribution. This lies in direct continuation of how Piaget's oeuvre was introduced to the North American continent by John Flavell in 1963. It would be interesting to now compare the sixth edition of this handbook, published in 2006; it is probable that the number of references to Piaget's theory will have considerably diminished. As an example, the keyword Piaget does not gather a very high number of references in the index of the recent *Oxford Handbook of Developmental Psychology* (Zelazo, 2013). It is also to be noted that the editor of this impressive handbook, in his introduction, does not quote Piaget, except for the emergence of new representational formats described in the *Construction of Reality in the Child* (Piaget, 1937/1954).

Beyond Piaget's Theory

The Piagetian theory is certainly still very active in developmental psychology and in education; many researchers around the world continue working with Piagetian tasks, even though they do not always acknowledge it, or even know it. From a theoretical point of view, the core part of the theory has been retained while giving rise to new developments, as should be the case with any sound theory. Only some concepts were really abandoned, the best example of which is the logicization of overall structures.

At the time the present notice was first written (first edition of the present encyclopedia), two directions appeared promising for the future while very close to Piaget's proposals, namely, the neo-Piagetian models and the application of dynamic systems modeling to developmental psychology. The objective of the neo-Piagetian models, initiated by Pascual-Leone and exemplified by scholars such as Robbie Case, Kurt Fischer, Graeme Halford, and Robert Siegler in the 1980s and 1990s (e.g., Case, 1992; Case and Edelstein, 1993; Pascual-Leone, 1987; de Ribaupierre, 1997, 2007), was to provide a response to some of the questions left open in the Piagetian theory by combining it with the cognitivist and the learning traditions. These models have in common the search for isomorphisms or invariants across different classes of situations. They maintained or rehabilitated (after the emphasis on domain specificity strong in the 1970s) the notion of general stage; however, the structuralist characteristics are quite different from those postulated by Piaget. First, the hypothesis of a unique, general, logical structure underlying the organization of all behaviors at a given moment of development was abandoned, and replaced by more local ones, thereby granting more importance to context and to specific processes. Second, isomorphisms across domains are considered to result from common constraints or 'strictures' rather than from a common structure: general limits in processing resources or attentional capacity impose a ceiling on the complexity of cognitive performances while allowing for situational and individual variability. Third, the importance given to context has as corollary a much stronger emphasis on task analysis, that is, on an analysis of the characteristics of external situations together with a fine-grained analysis of the strategies that children adopt when confronted with these situations and of the processing load that these strategies entail. Fourth, some neo-Piagetians also assign a more fundamental status to individual differences; consequently, they claim that there may exist different developmental paths for different types of subjects. This implies that development is no longer led by a single, dominant general mechanism such as equilibration, but that several general mechanisms may interact to produce development, leading to a postulate of multidimensionality and multidirectionality in development (Reuchlin et al., 1990; Rieben et al., 1990). Such a postulate has long been adopted by life-span developmentalists (e.g., Baltes et al., 1998), but took longer to be envisioned by child developmentalists.

Another promising way of theorization is provided by nonlinear dynamic systems theories (e.g., Fischer and Bidell, 2006). Such models can be used to detect, and then model, developmental transitions, that is, changes from one stable mode to another. The emphasis is on self-organization, which can be linked to Piaget's concept of equilibration. Although some scholars have begun to use nonlinear dynamics to build specific models of processes of development, particularly in the field of motor development or in conservation tasks (e.g., Thelen and Smith, 1994, 2006; Van Geert, 1994, 2003), these are not yet fully implemented nor operational; moreover, they require heavy methodological designs. Nevertheless, such attempts, which may help uncover discontinuities, i.e., stages, under what appears to be continuous change, could help bring explicit modeling into developmental psychology.

A number of new directions and emphases have also taken place, without explicit reference to Piaget; yet they seem very compatible. To quote only a few of those: theory of mind, role of executive functions, stress on a biological approach. A flourishing direction, that of the 'theory of mind,' was introduced without any reference to Piaget. Yet it is very compatible with the Piagetian theory, even though Piaget and his collaborators did not develop experimental situations in which children would be investigated with respect to their theory on humans in contrast with physical objects, except perhaps in Piaget's very early work (e.g., Piaget, 1932). On the one hand, the type of

paradigm used is close, taking the form of an interview; on the other hand, interest has been brought to the type of errors committed and not only to the age at which theory of mind is 'achieved.' Piaget never used the term 'executive tasks' or 'executive functions,' which constitute a significant part of the present day developmental psychology (e.g., Carlson et al., 2013). Yet, most Piagetian tasks would be considered as executive tasks. The close link established between executive functions and the functioning of the cortex, as well as the rapid growth of the cognitive developmental neuroscience would certainly have pleased Piaget who was criticized for having granted too important a role to biological factors.

Abstract

The article examines and reinterprets Piaget's central theoretical tenets and their implications for contemporary educational practice. The author argues that Piaget's theory posits human activity as the basis of human knowledge and human development. For Piaget, human activity drives and generates development, at each stage, creating qualitatively new ways of knowing and relating to the world. This interpretation emphasizes the connectedness of mental processes to the world in which, and through which, development takes place and the agentive role played by subjects who transform their world through active engagement. The implications that the theory has for education and the applications that derive from Piaget's theoretical formulation is examined.

Introduction

Born in Neuchatel, Switzerland, in 1896 – and having a solid background in the biological sciences and obtaining a PhD at the age of 22, after studying the behavior of molluscs, Piaget's theory of human development grew out of the contradictions of his early to mid-twentieth century society, contradictions that characterized the apparent tranquil of the society in which young Piaget grew up. Perret-Clermont (1997) provides an examination of the sociocultural context in which Piaget developed his theory to illuminate the meanings Piaget placed on his system of theorizing, most of which may remain implicit in contemporary debates of this theory. The social context of Piaget's Switzerland, as Perret-Clermont suggests, was characterized by conflict between religion and science as well as forms of traditional authority structures. Meanwhile, scientific Darwinism was in its ascendance and provided supposedly rigorous scientific account of biological and social processes (see Stetsenko, 2008; Perret-Clermont, 1997).

Piaget formulated a theory of human development that derived its explanatory principles from biological processes without, however, reducing complex human psychological phenomena to purely biological adaptation (Piaget, 2001). Therefore, Piaget sought to provide an account of the origin and development of knowledge that emphasizes relational processes between the individual and his or her environment or social situations. The relational processes are based on activities carried out simultaneously in the social and material world in which, and through which, development occurs; leading to transformation of self and – at the same time and within every stage – acquisition of qualitatively new modes of relating to the world; as well as new modes of knowing.

This article provides a general outline of Piaget's theory of human development and examines the implications this theory has for education. The discussion begins with a brief outline of the behavioral accounts of learning and development to which Piaget's theory stands opposed. Piaget's theory of human development is examined in more detail, with the main tenets of the theory and its major conceptual grounding elaborated. Lastly, the application of the theory to education is examined with a view to demonstrating the continuing relevance; and enduring significance, of Piaget's theory of human development to education.

Piaget versus Behavioral Explanations

Piaget's greatest impact in the social sciences lies – arguably, in his critique of the behaviorist explanatory framework and its depiction of human psychological processes as comprising habit formation produced through reactions to the effects of environmental stimuli (see Piaget, 2001, 1964). Behaviorism, as psychological tradition, sought to explain human psychological functioning using the same explanatory principles as those used in the natural sciences; thus seeking to establish the causal relationships between environmental conditions on the one hand and human behavior on the other – with the former conceived in terms of stimuli and the later in terms of responses. The stimulus–response framework, as the behaviorist tradition was alternatively called, posited that human actions, including learning, were the result of conditioning or habit formation as a result of positively reinforced responses to stimulus effects. Thus, the human mind was conceived of in terms of external associative relations between responses or reactions to the effects of environmental forces termed stimuli. Behaviorism ruled out the existence of mind as it assumed this to be not amenable to scientific verification through experimental methods similar to those employed in the natural sciences. Only studying the growth of behavior as resulting from the process of habit formation; occurring through conditioning or habituation of positive experiences, could, according to behaviorists, lead to a valid, scientifically rigorous form of knowledge of the human condition (Piaget, 2001, 1964).

While Piaget's theory resonates with social learning theorists such as Bandura and Mischel, the position of the social learning theorists further supports the view of human subjects as purposive, goal directed, and self-regulative rather than driven by environmental influences. As in Piaget's assertion about the centrality of human self-regulative processes and, hence, active self-directedness, Bandura (2001) posits a view of human agency premised on the essential conditions of human intentionality, purposeful pursuits, and self-reflectiveness. This view, as in Piaget's system, contradicts the mechanistic view of

human nature; proposing a picture of human condition as essentially subordinate to, and arising as mere responses to, external forces of environmental stimulation. For Bandura (2001) human activity is essentially agentic and driven; not by nature itself, but by a new functional structure created through and out of human agentic conditions.

In this system, humans exercise self-control over their thoughts and actions rather than being mere reactionaries to external forces. Their actions and thoughts are agentic and therefore involve qualities of intentionality, purposefulness, goal-directedness, forethought, planful proaction, aspiration, self-appraisal, etc. These agentic qualities function within fundamentally active (rather than reactive) and self-regulative human essence.

In a similar vein, Mischel (1973) states that self-regulatory systems involve self-control through self-imposed goals and self-produced consequences for action. That is, persons have the capacity to set performance goals for themselves and react to these with self-criticism or self-satisfaction, depending on whether they deem their performance consequences as meeting their expectations and criteria. Achievement of performance goals will most likely lead to positive self-appraisal, self-gratification, and self-reinforcement, while perception of failure may result in self-condemnation, anxiety, and desperation. The essence of self-regulatory system, according to Mischel (1973), is the subject's adoption of contingency rules, which are important to guide action and specify which behavior is appropriate under specific conditions. Social learning theories resonate with Piaget's system and could be employed to expand on its explanatory power, especially where personality differences in cognitive performance are to be accounted for. Piaget's unparalleled contribution to developmental psychology resides in his account for the genetic origin of active; and self-regulative, essence of human condition through his theory of human development.

Piaget's Theory of Human Development

Piaget posited an all-important construct of equilibration, on the basis of which internal mental processes can be comprehended. For Piaget, the child did not acquire knowledge through reacting to the effects of environmental forces and, as a result, building habits that become crystallized into forms of behavior. The construct of equilibration suggests that the subject is fundamentally active in his or her interaction with the social and physical environment and organizes his or her actions into schemas and structures, on the basis of which further construction of knowledge becomes progressively possible. That is, the subject regulates his or her own actions in the world and, in turn, these actions and the consequences they have, internally, into means for controlling own thinking; by establishing internal anticipatory schemas and structures on the basis of which further acquisition and development of knowledge becomes possible. The concept of equilibration, therefore, unlike the stimulus–response concept of behavior, resuscitates the idea of mind – an abstraction which defines complex forms of human consciousness. From Piaget's point of view, therefore, a rigorous, scientific methodology (scientific – though not in positivistic sense) that employs observation and clinical experimentation could be employed to study the origin, development and functioning of the human mind; without need to resort to the causal explanation of the behaviorist framework.

Equilibration involves two complementary processes of assimilation and accommodation. Assimilation involves an active integration of knowledge into preexistent mental structures. Accommodation involves the internal balancing processes whereby modifications within the existent structure or mode of knowing are carried out, so as to comprehend new knowledge effectively and hence, retain a state of balance or equilibrium to the hitherto disequilibrated structures (see, Piaget, 1964, 2001). Accommodation happens when a state of necessity for change arises on the part of the subject or when the subject becomes aware of discrepancies between his or her state of knowing and new knowledge to be assimilated. Therefore, the two processes of assimilation and accommodation are complementary, the former accounting for the process of learning while the latter accounting for development. That is, development is accounted for as involving qualitative changes that happen in existing structures, necessitated by the realization and the internal need for change, brought about by the awareness of a state of imbalance or state of disequilibrium between new knowledge to be acquired and existing forms of knowledge on the part of the subject.

Piaget argued that learning is explained through the process of assimilation – which, although it involves an active; rather than passive, integration of knowledge into preexistent structures, does not, however, change the structures or existing modes of knowing. What changes, rather, is the knowledge being assimilated, as this is transformed so as to fit into existing mental structures. Thus, knowledge of the world is not imprinted into the subject and the environmental forces do not determine knowledge to be acquired, in the sense assumed within stimulus–response systems. Rather, the subject is active – not in an aimless, purposeless, and trial-and-error fashion characteristic of the operant conditioning models of later stimulus–response frameworks; that sought to explain human learning in ways similar to habit formation processes established through animal behavior-change or conditioning experiments. Piaget's subject, or a child, is active in a purposeful manner where he or she acts on the world to master and comprehend it, and this action leads to internal mental coordinations; a process explained through the concept of equilibration.

Equilibration is therefore a motor for human development and this self-regulatory process emphasizes an active role the subject has in the acquisition of knowledge; which, although arises externally through the relational processes involved during the subject's interaction with the world, is, however, coordinated from within, since it is the subject, ultimately, that acts and comprehends the world in terms consistent with his or her existing structural organization. There is a sense of a biological adaptation involved in this process. However, Piaget termed this functional adaptation, in that it is not adaptation to the external world per se, but to the evolving structural organization or internal coordination of knowledge (Piaget, 2001). That is, the subject does not adapt to fit his or

her existing knowledge to the form of knowledge encountered from the outside, in his or her context of learning and development. Rather, the subject adapts to his or her existing; and yet, evolving conception of the world that he or she continuously modifies as and when the need – or a feeling of necessity, arises because the present state of knowledge is now deemed inadequate and creates dissonance that needs to be compensated. Piaget (1964), using the language of the behaviorists to critic their model of learning, argued that the response was present long before the stimulus effects – in the sense that it is not the external environmental forces that determine; in an associative form, how the subject reacts, but the subject's own, already constructed modes of knowing or knowledge structures.

Therefore, Piaget provided a solid, genetic account of human intellectual development grounded on human activity. First, the explanation emphasized genesis or developmental origin and, therefore, solving the problem of nativists or philosophical frameworks that subscribed to the notion that knowledge was inborn. Second, the account emphasized developmental progression – conceived, not as a quantitative accumulation of knowledge; as the behaviorists have contended, but as involving qualitative transformation of knowledge from its simpler forms to its more complex forms; characteristic of adult forms that – ideally, enables elaboration of logical and scientific knowledge often privileged in social institutions such as formal schooling.

From a genetic point of view, action; according to Piaget, comprises the basis of human knowledge. Unlike the behaviorists, action – for Piaget, did not only involve the physical aspect of human behavior. Action is both concrete and physical, as well as mental and abstract. This account of action simultaneously elaborates on the essential nature of experience, which in the stimulus–response system has been assumed to constitute only the external aspect of human interaction with the physical and social environment. Piaget, on the contrary, argued that action comprises both the external experience of the world involving; first, the subject's interaction with concrete objects in the world and; second, the consequences of actions initially effected to objects in the world. That is, the subject experiences the world through his or her direct interactions with it but eventually turns these experiences inward into his or her internal plane, where coordinations are subsequently conducted mentally. The former type of experience is considered to lead to operative forms of knowledge – that is, knowledge of how to relate to the world externally while the later type of experience is considered to lead to figurative forms of knowledge, which enables the knowing of the world through mental abstractions. Therefore, experience of the former type is externally directed toward the world while the experience of the later type is internally directed, toward mastery of self. It is, therefore, this mental action that leads to mental coordinations. The coordination of a series of actions leads to what is termed a mental structure. A series of these structures combine to form an operation. Piaget defined an operation as a series of actions that are reversible; that is, actions that have been organized into a reversible structure. These operations become the basis of meaningful, reflective activity through which the human mind is able to engage in interpretive, comparative, evaluative, and analytic activities (Piaget, 1964, 2001).

Sensory-Motor Stage

The genetic approach traces the origin of operational knowledge from its developmental origin in the earliest forms of human activity – the sensory-motor actions, which serve as the early forms of mental coordinations. The coordination of sensory and motor actions leads to the construction of schemas or early structural organization of thought; leading to the acquisition of the concepts of space, time, causality, and object permanency. For example, Piaget found that children acquired the notion of object permanence around 18 months. That is, the child becomes aware of the fact that objects continue to exist even when they have been removed from its spatial field – and do not, therefore, cease to exist. The maturational processes of the nervous system are connected to the development of sensory and motor activities and therefore make possible; and are transformed into, developmental processes. The child progressively masters the world through interacting with it – assisted primarily by its sensory and motor activities and as a result begins to construct – mentally, the functional knowledge of the world around it.

Piaget (1964, 2001) provides an example of a sensory-motor child attaining the concept of object permanence through the coordination of experiences and hence the acquisition of a notion that objects do not disappear and cease to exist when removed from visual field. As evidence to the acquisition of this concept is the child's changed behavior with regard to his or her interaction with objects; where by 18 months the child begins to search for objects outside of its visual field, with the goal of finding them located somewhere. With this acquisition is, of course, also the acquisition of the related concept of space, which arises out of the special coordinations that characterizes sensory-motor activities.

The end of the sensory-motor stage heralds the dawn of preoperational thought around the age of two. By this stage, one begins to see the emergence of structural organization of thinking in the form of operations or systems of actions that are internally connected. However, these early forms of thought structures are characterized by the lack of 'mobility' or backward-and-forward movements – a fluidity that progressively resembles the logical and mathematical forms of thinking considered; within this theory, to constitute the apex of knowledge development. While the sensory-motor stage enables mastery of the physical world through coordination of experiences; a process that weans the subject from greater dependence on the effects of environmental forces characteristic of perceptual processes, the preoperational stage increases this distance from reliance on the effects of the environmental forces. This process is primarily facilitated by the development of symbolic forms of relations that characterize the social world and; specifically, the use of language (Piaget, 2001, 1964).

Preoperational Stage

Piaget posited that the preoperational stage emerges around the age of 2 years and concludes at around the age of 4/5 years.

There has been much debate of the actual age range at which this stage concludes. This is not surprising considering that Piaget's experimental work emphasized children's deficient performances on tasks that required reversible forms of mental operations for successful completion – an approach which, perhaps, was unduly influenced by his early work with children at Binet's laboratory. At this stage, Piaget found that children could not perform conservation tasks competently.

Piaget described the preoperational stage predominantly in terms of the child's inability to carry out operational thought or to understand conservation tasks – involving the ability to understand forms of knowledge that require reversible or reflective thought processes. That is, preoperational children were found to lack the ability to comprehend situations where two or more categories are to be held constant – in perspective, in order to arrive at valid conceptualization of a situation.

For example, Piaget presented a number of experiments in which preoperational children were not able to conserve or comprehend quantity, weight, volume, etc. One of the most common of these conservation experiments involved the conservation of quantity that is transferred from a shorter and wider glass container to a taller and narrower glass, thus showing a changed appearance in the taller container; falsely suggesting an increase in quantity. The transfer of quantity is performed in the presence of the child and the child is asked if we now have more or less quantity in the second container as a result of the transfer process. Preoperational children were found to lack full comprehension of the situation, focusing exclusively on the changed appearance of quantity in the taller glass and, as a result, insisting on the notion that there is an increase in quantity (Piaget, 2001, 1964).

Piaget argued that a preoperational child lacks the ability to hold two categories constant and to use full information to arrive at a solution to the problem. That is, the preoperational child is inclined to focus only on one aspect of the problem and to use only this to arrive at a solution of the problem because he or she does not as yet have cognitive ability to hold two or more perspectives constant and to use these simultaneously as cognitive resources for getting to a solution for the problem. This lack is necessitated by the nature of the developmental stage that characterizes the child's present cognitive functioning. The preoperational child must consolidate on his or her knowledge of the world that the sensory-motor activities have enabled him to construct and progressively integrate this knowledge with the form of knowledge that derives predominantly from his or her internal, mental coordinations – a form of knowledge that should lead, not just to mastery of the external world, but also to the mastery of self.

During the preoperation stage, the child's cognitive development is dominated by the need to master self and actions are predominantly directed towards self-mastery and, as a result, the child lacks the ability to 'decenter' (Piaget, 2001). That is, the preoperational child lacks the ability to see things from other people's perspective as he or she insists on own point of view. Therefore, the dominant mode of thinking during this stage is egocentric, making it difficult for the preoperational child to coordinate thinking to arrive; through analysis, at valid solution to the problem. This inability could indeed have negative impact on the acquisition of numeracy and literacy skills should the preoperational child be placed within formal learning situations in school. This difficulty may arise, for example, from the inherent nature of formal learning such as the requirement in reading acquisition; simultaneously, to focus both on the phonemic (requiring the understanding of relations between speech sounds and letters of the alphabet) and the semantic (or meaning-making) aspects of the reading process.

However, an undue emphasis on the cognitive deficiencies of the preoperation stage, as was characteristic of the dominant approaches in Piagetian cross-cultural research, was unfortunate. Positive developmental milestones are achieved during the preoperational period, and this stage serves as good preparation for acquisition of operational forms of thinking. For example, preoperational children acquire the capacity for symbolic representation, of which language development is a crucial component. The preoperational stage is crucial for children to gain mastery of themselves in relation to their growing participation in the world of adults. The preoperational stage is characterized, among other things, by the development of language. Language development during this stage, however, takes a particular form that is consistent with the character of the stage itself. The child acquires language and its symbolic function, but the entire acquisition is oriented toward self-mastery. For example, the preoperational child uses same words acquired during interaction with adults but attaches idiosyncratic meanings to these. Also, the preoperational child may verbalize his or her thoughts as a way of controlling own actions, such as during situations when the child needs to commit something into memory. Meanwhile, the preoperational child plays with toys or objects in his natural environment in creative ways. For example, a brick may be turned into a bus; a piece of wood may become an airplane, etc. In this way, the preoperational child acquires the ability for symbolic representation, important both for language development and social functioning; as well as for learning the various subject matter during formal schooling later on when the child has reached school-going, concrete-operational stage. The significance of egocentric forms of language in particular; and thinking in general which characterize the preoperational stage, has – interestingly, been elaborated outside of the Piagetian framework (see Vygotsky, 1986 for this elaboration).

Concrete Operational Stage

Fortunately, for the school-going child, the forms of thinking required for successful learning of the formal knowledge characterizing the subject matter has already appeared in the child's mental capacities. The cognitive capacities for reflecting on own and other people's perspectives; for comparison and analysis, has already made their first emergence into the cognitive repertoire of the child. That is, all the deficiencies that characterize the preoperational stage are overcome at the concrete operational stage. However, the child still needs the support of concrete activities to carry out operational processes comprehensively. The concrete operational child can, for example, make the necessary analysis of the situation; taking into account all the information available to him or her, and arrive at valid conclusions about the quantity transferred from one glass

container to the other as described earlier. The concrete operational child would insist that the same quantity remains after transfer to the second container because the activity of transferring from one container to the other did not comprise adding to; or taking out from, the available quantity. Therefore, quantity is conserved because all available information constitutive of the situation is taken into account in arriving at a solution to the problem. According to Piaget, this knowledge is not attained through simple accumulation of experience. It is the result of the internal self-regulatory activities of the human mind and comes about as a result of qualitative changes that comprise human mental development.

However, while the concrete operational child is able to understand conservation tasks such as the one involving the constancy of liquid quantity, his or her thought processes are still reliant on concrete activities. That is, thought coordinations that involve reflective and reversible systems of ideas and concepts still rely, predominantly, on concrete situations and objects in the subject's experiences. This idea of concrete operations has mostly been misinterpreted to mean learning through concrete objects. However, while concrete objects could be crucial in getting the preoperational child understand complex ideas, they should always be employed as a means to an end and not as an end in themselves; the end being to generate capacity for analysis, comparison, and reflective activities carried out mentally without dependence on external props. For example, teaching children to carry out basic arithmetic operations of addition, subtraction, division, and multiplication through use of pebbles or abacus (which is a form of employment of concrete objects) should always be aimed at getting them to master these skills 'internally' or inside their mind as abstract cognitive activites. That is, the learning that happens here should be oriented toward the interiorization or internalization of these concrete activities into the internal plane of cognitive functioning.

In terms of children learning in school, the concrete operational stage is critical for laying good foundations for successful learning. Many things could go wrong during this period in cases of poor teaching and learning provision. For example, Muthivhi (2010) and Muthivhi and Broom (2009) studied concrete operational and formal operational learners whose learning was characterized by the forms of teaching that did not prepare them adequately for; and elaborate on, the reflective processes necessary for successful learning of the formal subject matter knowledge. These studies found that, although these learners demonstrated levels of performance consistent with normal developmental stages, they tended to be overreliant on concrete manifestations of the tasks and often derived conclusions to problems from their perceptions of the concrete situation rather than from their conceptualizations of the situation; taking full account of all available information to arrive at valid conclusion.

Formal Operational Stage

During the concrete operational stage, the child is consolidating a particular form of thinking that characterizes the social world of adults – the world of reflective, interpretative, comparative, and analytic activities; all of which are activities of the human mind, which, of course – as Vygotsky (1978) has argued, are dialectically related to the activities of society and culture. Piaget termed this stage in human development, the formal operational stage and focused predominantly on the acquisition and development of the formal activities of the human mind, which he alternatively referred to as the 'logicomathematical' processes (Piaget, 2001, 1964). We can understand this specific emphasis to be influenced by the idea of the 'true forms' of human thought, unencumbered by social traditions and adult impositions, which; of course, had its history in the philosophical traditions of Emmanuel Kant's proposition of the basic categories of thought as involving 'number, space, causality, and time' (Piaget, 2001, 1964; see also Shayer, 1997).

Therefore, Piaget, sought to understand how human individuals – what is termed ontogenetic development – came to acquire the basic categories of the human mind that underlie the formal processes of human thinking; characteristic of the formal activities of scientific and mathematical practices. As a result, logical processes of thought; their origin and development from early adolescent to adulthood, became the main emphasis of Piaget's research. Where he included psychological processes other than those related to the logical processes; such as language development, the role of the social and emotional development, the focus was on how these processes were related to, and could be explained from the vantage point of the functioning of logicomathematical processes.

For Piaget, the formal operational thought, the onset of which begins in early adolescence, marks children's first entry into the world of adults; in the sense that children begin to acquire the forms of thinking and attitudes to the words that are primarily informed – not by how things appear in the world – but by how the world makes sense to them from the point of view of their own interpretations and analysis of situations. That is, they enter the world of thoughtful existence; the world of abstraction, of logical and propositional forms of thinking where the world – and knowledge – is; essentially, a product of mental coordinations. Formal operational children, or – more precisely, adolescence, may; for example, begin to question the status quo and existing social traditions as well as the taken-for-granted world of adults, even as they seek to enter and have meaningful existence in it – hence the radical changes often experienced in the behavior of adolescence.

Clearly, this stage presents positive challenges and opportunities for teachers as these learners are naturally very curious and inquisitive. Piaget's framework, therefore, points to a model of education that is explorative, investigative; as well as directed by the curiosity and inquisitiveness of learners, and curriculum development initiatives that could exploit this golden opportunity to engage learners and involve them in an ongoing quest for, and creation of, knowledge. However, young adolescents are often put off by the traditional forms of education, still widespread all over the world, which focuses on drilling of stale, factual knowledge, often putting pressure on learners to learn most of the subject matter by heart or through quasi-meaningful processes of committing rules and procedures to memory so they could remember them for use as tools to work out solutions to given problems (see Arievitch and

Table 1 Major developmental stages, their approximate age ranges, and the dominant activities that characterize them

Major developmental stages	*Approximate age ranges*	*Dominant cognitive activities*
Sensory-motor	0–18 months	Maturation, sensory and motor coordination
Preoperational	18 months to 5 years	Self-mastery through egocentricism, symbolic representation and early language acquisition
Concrete operations	5–11 years	Decentration, self-monitoring, reflection, analysis, and comparison necessary for logical–operational activities applied to concrete situations and concrete objects.
Formal operations	12 years to adulthood	Logical thought processes proceeding from abstract categories and less dependent on concrete objects and situations. Self-monitoring, self-reflection, analytic and comparative activities, and increasing abstraction of thought processes.

Stetsenko, 2000 for a detailed discussion of traditional methods and their epistemologies). It was for this reason, therefore, that Piaget opposed and doubted the capacity of educational processes to contribute to children's development and their desirability as a means of accelerating development (Table 1, summary of the stages of development).

Application of Piaget's Theory to Education

Piaget's theory has important implications for educational practice. Its influence on modern education is unparalleled. Importantly, Piaget's theory has contributed immensely in transforming the way in which children are conceptualized and hence, how they could more effectively be educated. For Piaget, as could be seen from the foregoing discussion, children are essentially active and do not therefore learn by passive reaction to stimulation around them. That is, they do not learn by passively receiving knowledge from the world around them but actively; through their own agency, transform the world in which they live in order to know it. That does not mean, as others assumed, that children should be left to their own devises or that adults have no role to play in the life of the developing child. However, Piaget cautioned against schooling, and related social systems that provided a child no room to come to the knowledge of the world through his or her own intellectual means; denying children their inherent disposition to know the world in ways that make genuine sense to them.

Piaget posited a child who is actively constructing his or her knowledge of the world through transforming it and thereby also transforming himself or herself. That is, the child knows the world through his or her existing but yet transforming (rather than just static) intellectual capacities. These capacities – as the discussion of the inherent connectedness of the stages to the dominant forms of the child's activity in the world has shown above – are not reducible to individual or social moments of their manifestations. Therefore, learning and development in Piaget's framework, although foregrounding the primacy of the individual in ontogeny, does not suppose a child or childhood as completely autonomous of, and discontinuous with, the society and culture in which children's learning and development take place.

Therefore, teaching informed by the Piagetian theoretical system would proceed from the assumption that children at specific stages of development; such as the age of 6 years, would be able to carry out reflective processes, provided that these are supported by concrete phenomena with which they engage and on which their cognitive functions are applied. The concrete nature of thought processes for the concrete operational child is, however, not limited to the use of concrete objects. Although the use of concrete objects is important and should be encouraged at this stage, this should, however, be employed as a means for getting the child master complex demands of tasks such as carrying out number of operations that may require the support of counters or abacus, for example. That is, the employment of concrete objects becomes a means to an end, the end beings the transformation of the child's thinking towards abstract forms of thinking; where thought processes are increasingly carried out without the need for reliance on concrete support. That is, learners at elementary school levels such as those in the age ranges of 5.5–7.5 years could benefit from instruction that employs concrete objects and examples to illustrate complex ideas and models, as well as arithmetic principles and operations. However, such employment of concrete objects and examples should be employed as a means for helping learners to acquire an idea or principle that they would later employ on their own in solving related problems; and base their future learning of complex knowledge on the foundational ideas and concepts initially acquired through the help of concrete objects and empirical illustrations.

Symbolic or semiotic systems that underpin the learning of reading and writing as well as basic number operations could be acquired in this way. An understanding of the principles for a pedagogy that derives from Piaget's system may be crucial for educators to relate knowledge to early school learners more effectively in ways that contribute deep level learning and development. For example, Piaget's system posits that children during early formal school years are capable of employing complex mental capacities, involving holding two or more perspectives simultaneously. Contemporary research on school children's use of cognitive capacities; comprising the ability to hold two or more perspectives simultaneously during problem solving, suggests that while these capacities may owe their development in children's spontaneous

activities (everyday-life activities that do not necessarily involve teaching), their elaboration and conscious application to problem situations may be constrained if classroom instruction does not foster their conscious application to problem situations (see, Muthivhi, 2010; Muthivhi and Broom, 2009; Shayer, 1997).

For Piaget, the acquisition for this cognitive capacity demonstrates an important shift from self-centered, egocentric thought processes – where the child is not able to consider two or more relevant aspects of a situation to arrive at a valid conclusion – to a 'decentered', self-regulative and reflective form of thinking that characterizes operational thinking of school-going children. Piaget (1964, 2001) has posited symmetrical social relations as necessary for the development of self-regulative thought processes. Symmetrical relations involve relations of mutual epistemic respect and epistemic equality. Epistemic, in the sense that the equality and mutuality involved is necessarily in respect of intellectual engagement, exchange of ideas, adherence to the rules of engagement in pursuit of knowledge and novel ideas, as well as models of knowing the world and self. This view contrasts the assumption that the social in Piaget is solely, and exclusively, in respect of children's relations to – and collaboration with, each other (see, for example, the discussion of the social in Piaget's theory in Shayer, 1997; Perret-Clermont, 1997; Labouvie-Vief, 1996). Contrarily, the notion of mutuality can be employed by teachers to model forms of classroom engagement that foster relations of epistemic equity and mutuality that generate pedagogic situations conducive for genuine learning and cognitive development (see; for example, Ginsburg and Allardice's, 1984 Piaget's inspired model). Meanwhile, the notion of epistemic equity and mutuality can also be employed to organize group-based, collaborative learning activities that contribute to learners' self-regulative, reflective engagement with the world and with novel ideas that come from the subject matter of their classroom learning.

Vygotsky's Framework as a Competing Paradigm

It was, ironically, in its capacity for application to educational settings; to provide solutions to most pressing challenges of educational underperformance, conceptual understanding, and task mastery, that Piaget's theory of the origin and growth of knowledge has failed to make significant advances. Piaget's theory was particularly critiqued for not taking adequate account of the social and cultural factors in its account of cognitive development and functioning and therefore as limited in its possibilities for application to classroom teaching and learning situations. Vygotsky's theoretical system was, on the contrary, credited for doing precisely what Piaget's theory was considered to have failed to achieve, that is, foregrounding the role that sociocultural processes play in human development (e.g., Matusov and Hayes, 2000).

The most powerful among current critiques of Piaget's system probably relate to his view of development as proceeding by way of adaptation – as a form of biological adaptational process. Vianna and Stetsenko (2006), for example, argue that Piaget, by positing a view of children as developing and learning in the spirit of adapting to existing conditions, and mind as evolving out of actions through which people adapt to the world, presents a limiting picture of the human condition. Vygotsky, on the contrary, positing a view of children developing and learning as they actively change the world they live in – simultaneously changing themselves and gaining knowledge of themselves and of the world, presents a position that transcends the constraining picture of humans as changing to fit in with the world into which they contribute nothing towards its transformation.

Conclusion

Piaget's theory of human development has made an enormous contribution to contemporary educational practice. By revealing that children think differently from adults; that children are not little adults in the making, and that their thinking differs from that of adults not only in quantitative terms but in the quality of thought processes involved, Piaget made a lasting contribution to our knowledge of how teachers could appropriately relate to learners, as well as how knowledge could effectively be organized at different stages during children's development.

The theory inspired many educational models such as learner-centered approach, discovery-based learning, activity-based learning, collaborative learning, constructivism, exploratory learning, and active enquiry-based learning models. These, and related educational models that derived from Piaget's theoretical systems, had an immense influence on many educational systems across the world. All of these models, inspired by Piaget's framework, proceed from a common ontology, a worldview that learning is a process that is fundamentally driven, first and foremost, by the activity of the learner – and not necessarily by the actions of teachers or needs of society, with existing social structures serving as unalterable *telio* or end-point of human development.

Pidgin and Creole Languages

Salikoko S Mufwene, University of Chicago, Chicago, IL, USA

Abstract

The study of creoles and pidgins has been marked by controversy about how they emerged, whether they can be identified by their structural features, and how they stand genetically in relation to their lexifiers. There have also been disagreements about what contact-induced varieties count as creoles, whether expanded pidgins should be lumped together with them, otherwise what distinguishes both kinds of vernaculars from each other, and how other contact-induced language varieties can be distinguished from all the above. Another important question is what they contribute to the understanding of language from the phylogenetic, typological, and sociolinguistic perspectives.

Introduction

The neutral word order *Creole and Pidgin* is used deliberately in the title of this article, because the traditional position that creoles evolved from erstwhile pidgins has been questioned, on the grounds that it is not supported by the history of colonization, which produced both kinds of language varieties (Chaudenson, 1992, 2001, 2003; Mufwene, 2001, 2005, 2008). Much earlier, Alleyne (1971) had disputed the 'baby talk' hypothesis, according to which creoles (and pidgins) had evolved from simplified varieties of European languages in the contact settings that produced them; fossils of inflections still evident particularly in Haitian Creole and even in such others as Saramaccan and Sranan (e.g., *broko* 'break', *dede* 'died, dead') speak otherwise. Below, I will also connect these issues to the role of interpreters in the earlier stages of the contacts between Europeans and non-Europeans in both trade and settlement colonies. The reader will thus be served an account more grounded in the history of colonization than traditional a-historical ones such as Bakker (2009).

The label 'language varieties,' rather than 'languages,' is also used to draw attention to the fact that in many places where these varieties coexist with their lexifiers, their speakers do not think they speak a separate language, only a different variety (Mühlhäusler, 1985; Mufwene, 1988). Lexifier – the language from which a creole has evolved, having selected most of its vocabulary from it and, according to this article, even a great deal of its grammar, often with some modification. It has not been proven that creoles and pidgins may not be considered as new nonstandard dialects of the relevant European languages (see below), on a par with others that emerged in populations that are predominantly of European descent, worse yet, that they are not genetically related to their lexifiers, *pace* Thomason and Kaufman (1988) and Thomason (2001). Mufwene (2001, 2005, 2008) and DeGraff (2003, 2005) expose social biases in the ways linguists and other scholars have singled out creoles and pidgins as outcomes of abnormal or less natural evolutions.

The term *lexifier* is used in this article, as in much of the creolistics literature, as a label of convenience for the language (variety) from which a creole or pidgin has evolved and has typically inherited most or the overwhelming part of its vocabulary. The claim that a creole has typically inherited its grammar from sources other than its lexifier (Holm, 1988; Thomason and Kaufman, 1988; Thomason, 2001) is not backed by the diachronic evidence. Although a creole or a pidgin, often (mis)identified with the basilect, has a grammar very different from the standard variety of its lexifier (called *acrolect*), it has often been shown that much of its grammar can be traced, at least partly, to some of the nonstandard varieties to which its 'creators' were exposed. This is in fact one of the strongest contributions of Sylvain (1936), ironically invoked by some creolists as a forerunner of the relexification hypothesis (see below).

Although creoles and, to some extent, expanded pidgins (see below) have received a great deal of attention since the 1990s from a typological perspective (see in particular McWhorter, 1998, 2001; and the response by DeGraff, 2001), linguists have traditionally investigated them from the point of view of their 'genesis.' Space limitations make it difficult to focus equally on both research dimensions; this article focuses more on determining what kinds of language varieties they are historically, what peculiarities appear to distinguish them from other natural languages, and what they actually teach us about the role of contact in language evolution and about the architecture of language.

As much as the term *creole* has been extrapolated to various contact language varieties, including those with a non-European lexifier (cf Kouwenberg and Singler, 2009), this article is restricted to those lexified by a European language in those colonies where a European language prevailed as the vernacular to which all nonindigenous populations shifted sooner or later. The reasons for this position are articulated below.

What Are Creoles and Pidgins?

Strictly speaking, creoles and pidgins are new language varieties that developed out of contacts between colonial nonstandard varieties of a European language and several non-European languages around the Atlantic and in the Indian and Pacific Oceans during the seventeenth to nineteenth centuries. *Pidgins* typically emerged in trade colonies that developed around trade forts, such as on the coast of West Africa, and on whaling ships, as in the South Pacific. They have reduced structures and restricted functions (typically trade and whaling activities); and initially they served as

nonnative lingua francas to users who maintained their native vernaculars in their intraethnic interactions. Some pidgins have expanded into regular vernaculars, especially in urban settings, and are called 'expanded pidgins.' Examples include Bislama and Tok Pisin (in Melanesia) and Nigerian and Cameroon Pidgin Englishes. Structurally, these are as complex as 'creoles' (Féral, 1989; Jourdan, 1991, 2009), though their evolutionary trajectories are different (see below).

Creoles emerged in settlement colonies whose primary industry consisted typically of sugar cane or rice cultivation, for which non-European slaves or contract laborers were employed who constituted the overwhelming majority of the plantation populations. Examples include Haitian, Mauritian, and Seychellois (lexified by French); Jamaican, Guyanese, and Hawaiian Creole, as well as Gullah in the United States (all lexified by English); and Saramaccan and Sranan in Surinam (lexified by English, with the former heavily influenced by Portuguese and the latter by Dutch). Creoles have also been singled out in Australia, although there are no history Creole populations there. (Interestingly, as explained below, the initial Creole populations in the relevant colonies spoke not creoles but koiné varieties or closer approximations of these. (Koinéization, traditionally ill-defined as 'dialect-leveling,' is the compromise variety that emerges by competition and selection from the contact of dialects of the same language.) Nonetheless, Creole people are mentioned because the term for the colonial vernaculars is a historical derivative of that for people.) Vernaculars such as Cape Verdian Crioulo (lexified by Portuguese) and Papiamentu in the Netherlands Antilles (apparently Portuguese-based but influenced by Spanish) suggest that the plantation industry is not as significant a factor as population growth (including rate of population replacement) and population structure (having to do with early segregation) in the identification of a colonial vernacular as a creole. These considerations help explain why Brazil, which engaged in sugar cane cultivation a century earlier than the Caribbean colonies but had a different population structure, did not produce varieties identified as creoles. To be sure, it is also disputable whether these vernaculars can be singled out as a typological class (*pace* McWhorter, 1998, 2001), let alone a genetic one (see below).

Note that although Melanesian expanded pidgins are associated with sugar cane plantations, they need not be considered as creoles. As pointed out by Keesing (1988), they apparently originated in trade and whaling settings and were adopted as lingua francas on the plantations, in what Chaudenson (1979ff) considers as 'endogenous colonies,' before they evolved into urban vernaculars and expanded their functions and structures. Given that the complexity of their grammars makes them comparable to creoles (see also Siegel, 2008), they raise the question of whether only one evolutionary trajectory need produce this kind of restructuring away from the lexifier.

According to Chaudenson (1992ff), creoles have evolved by basilectalization (structural divergence away from the lexifier, leading to the emergence of a basilect in a creole continuum), from closer approximations of their lexifiers spoken by the earliest slaves. As a matter of fact, linguists have typically considered as creoles the basilectal varieties, which evolved later in history and are structurally the most divergent from the acrolects. These should not be confused with the protovariety identified as *lexifier*, which was typically nonstandard, possibly a colonial *koiné* of the relevant European language that prevailed. Thus one may argue that, evolutionarily, creoles stand to expanded pidgins in a way that a half-empty bottle stands to a half-full bottle: different histories but similar outcomes. Jourdan (2009) provides interesting evidence of very recent complexification of Bislama grammar from less complex structures and using materials from the English lexifier under the influence of substrate languages.

It has been assumed since the nineteenth century that creoles evolved from pidgin ancestors by the acquisition of native speakers and the concurrent expansion of the pidgins' structures to meet more communicative functions. However, history shows that creoles actually emerged in settings where contacts between Europeans and native speakers of the lexifiers could not have been as sporadic as in the trade settings that produced pidgins, certainly not during the homestead phase when the non-European component of the settlement population was the minority and the populations were racially integrated though not necessarily equal socially (Chaudenson, 1992ff; Mufwene, 1997). Geographically, creoles and pidgins developed in separate places, in which fluent speakers of the local vernaculars (who need not have been Europeans in settlement colonies) and the learners had differing interaction patterns, sporadic in trade colonies but regular and apparently also intimate in the settlement colonies (Mufwene, 2005, 2008). Moreover, the term 'pidgin' was first used in print in 1807 (Baker and Mühlhäusler, 1990), much later than the term 'creole,' which was coined in Latin America for locally born people of nonindigenous stock in the late sixteenth century and used in reference to a 'corrupted' variety of Portuguese spoken in Senegal in the late seventeenth century (La Courbe's *Premier voyage* 1688: 192, cited by Arveiller, 1963). Its later, exclusionary extension to other colonial nonstandard varieties spoken primarily by descendants of non-Europeans may have been initiated by locally born European colonists, who were proud to be identified as Creole (given some rights they could invoke to administer the colonies), claimed to have maintained the European language intact, but dissociated themselves from the non-European Creoles (Stewart, 2007).

The etymology of the term 'pidgin' points indeed to 'Pidgin English,' apparently a distortion of 'business English' (though it is probably also due to partial congruence with Cantonese *bei chin* 'give money' or 'pay'; Comrie et al., 1996, p. 146), in Canton, an important trade colony where no colonial plantation industry developed and no variety has been identified as creole.

More doubt on the traditional position that creoles evolved from pidgins is cast by the role that interpreters are shown to have played, in historical accounts, in the early contacts between Europeans and non-Europeans (Bolton, 2000, 2002; Fayer, 2003; Mufwene, 2005, 2014). This is best documented about China, where the interpreters (also identified as 'linguists'), from the indigenous ruling class,

were also required power brokers in trade (Van Dyke, 2005). The evidence also comes from the history of the colonization of Hawaii (Beechert, 1985), where interpreters from the monarchy are reported to have played a role in the spread of English, and that of Africa, where interpreters facilitated its colonization (Fortbath, 1977; Reader, 1997; Lawrance et al., 2006). There is also similar evidence about the colonization of the Americas, where interpreters were used in trade with Native Americans (Karttunen, 1994; Curtin, 1984; Gray and Fiering, 2000; Metcalf, 2005).

There are thus plenty of reasons to question the traditional, a-historical view that derives creoles from pidgins, still espoused by Siegel (2008), Bakker (2009), and a number of other creolists. Although the Pacific illustrates the pidgin-to-expanded pidgin evolutionary trajectory, this is not the evolutionary trajectory of creoles around the Atlantic and in the Indian Ocean, or even in Hawaii. One must always remember that, barring some questionable characterizations of some South-to-East Asian vernaculars as creoles, there is a neat ecological complementary division between creoles and pidgins: the creoles that have informed our theorizing typically emerged in plantation settlement colonies, whereas pidgins emerged in trade colonies or on whaling ships (Keesing, 1988). In Hawaii, Creole emerged in the city but Pidgin on the plantations (Roberts, 1998), which precludes extrapolating hastily from Hawaii to the Caribbean or vice versa, *pace* Bickerton (1981, 1984).

History also suggests that even pidgins may have evolved by gradual basilectalization, not at all abruptly, as the number of people using the trade language increased and most of the new users hardly had enough exposure to the varieties spoken by the earlier interpreters. Expanded pidgins of course arose by recomplexification, under the ecological pressure of the increased and more diversified communicative needs of those who would use pidgins as vernaculars. The often-invoked jargon or prepidgin stage has not been documented. Siegel (2008) associates it with isolated individuals who do not form a community where the new language works as an auxiliary lingua franca. The claim, which confuses interlanguages with the emergence of a new language variety, is also at odds with the role played historically by interpreters in the earlier stages of trade between Europeans and non-Europeans. We will learn more about the emergence of pidgins in doing more research about the conditions under which the interpreters were formed, undoubtedly by immersion, as suggested by the history of the discovery of the rest of the world by Europeans.

Last but not least, it is also noteworthy that no French pidgin emerged on the African coast that can be related to French creoles of the Caribbean and Indian Ocean; and English pidgin in coastal Nigeria (which spread into Cameroon after the Germans lost the colony) may be a late eighteenth to nineteenth century phenomenon (Mufwene 2014). As reported by Huber (1999) and confirmed by Ostler (2005), Portuguese had then functioned as the convenient lingua franca along the trade route all the way to the Far East (and the language of diplomacy in the same world) until after the Dutch, French, and English maritime powers confiscated some of the Portuguese colonies. The slave trade on the African coast appears to have been conducted in Portuguese, spoken by the *grumetes* and the children of the Portuguese 'factors' or *lançados*, who acted both as brokers/intermediaries and as interpreters (Berlin, 1998). Nigerian Pidgin may thus have arisen for reasons that had nothing to do with the slave trade. Tay Boy, the only French pidgin that emerged in colonial French Indo-China, may be a phenomenon similar to the *le français tirailleur* in West Africa (especially Senegal), thus recent (in the twentieth century), long after French creoles had emerged, and was short-lived. The present *Abidjannais*, the French lingua franca spoken by poorly educated Ivoiriens in the southern part of Côte d'Ivoire, is also a recent twentieth century phenomenon.

The terms 'creole' and 'pidgin' have also been extended to some other varieties that developed during the same period out of contacts among primarily non-European languages. Examples of the latter denotational extension include Delaware Pidgin, Chinook Jargon, and Mobilian in North America; Sango, (Kikongo-)Kituba, and Lingala in Central Africa, Kinubi in Southern Sudan and in Uganda; and Hiri Motu in Papua New Guinea (Holm, 1989; Smith, 1995). In the original, lay people's naming practice, the term 'jargon' may have been an alternate to 'pidgin,' though, like the term *patois* in French colonies, it had a much longer, precolonial tradition of being used for a language considered 'barbarous' or just 'unintelligible' to speakers of a language considered 'superior.'

However, for reasons that remain elusive, Hall (1966) and Mühlhäusler (1986) stipulate that pidgins are more stable and jargons are an earlier stage in the 'life-cycle' that putatively progresses from Jargon, to Pidgin, to Creole, to post-Creole by progressive structural expansion, stabilization, and closer approximations of the lexifier. As noted above, history provides no particular information that supports this position, though every second-language learner goes through an interlanguage stage as they develop their competence in the target language, which naturally need not be expected to match that of native speakers nor to be fluent. Although the interlanguage may be unintelligible to native speakers, learning a second language imperfectly (a phenomenon that varies in degrees and varies from one speaker to another) is not tantamount to being stuck in an interlanguage, *pace* Plag (2009), as pointed in Mufwene (2010).

The extension of the term 'creole' is more problematic largely because of its original association with nonindigenous people born in the American settlement colonies and later applications to plants, animals, and customs considered particularly typical of the same colonies (Valkhoff, 1966). It is thus that it was extended to some of the language varieties, while European Creoles did not want this characterization to apply to their colonial dialects (Chaudenson, 1992, 2001; Mufwene, 1997). This has in fact raised issues about whether or not Afrikaans as spoken by the Afrikaners is a creole. Hesseling (1897) saw it in a different light, as not a creole (in contrast with Negerhollands, produced by African slaves in the Virgin Islands), than Valkhoff, who called it a creole.

There are also varieties spoken by descendants of non-Europeans in pockets of small endogenous Portuguese settlement colonies from South Asia (e.g., Korlai in India) to Southeast and East Asia (e.g., Papia Kristang in Malaysia and Mecanese in Macau) that are called creoles. They are

not associated with the plantation industry, not even remotely (like Cape Verdean Crioulo), and do not match the epistemic prototypical stereotype of creoles developed from those of the Atlantic Indian Oceans, but they share with the latter the fact of being a nonstandard vernacular of European origin spoken by a non-European population. Less controversial is perhaps the case of varieties that developed in Northeastern Australia, which are products of largely endogenous plantation settlement colonization (as in Queensland), although this is only a partial characterization of Australia as a settlement colony.

In the absence of any conclusive evidence that defines creoles structurally, *pace* McWhorter (1998), it is not evident that the term *creole* can be extended to just any language that is claimed to have started as a pidgin and has been 'nativized' (see below). Thus, it should not be extended to expanded pidgins such as Melanesian pidgins and Nigerian and Cameroon Pidgin Englishes, as noted above. An important lesson from all this confusion is that population movement and language contact appear to have played a catalyst role in normal language change and language speciation, even in varieties not considered as creoles or pidgins (Trudgill, 1983, 2004; Mufwene, 2001, 2003, 2005, 2008; DeGraff, 2003, 2005, 2009).

The Putative 'Creole Life-Cycle' in Historical Perspective

The myth of this evolutionary trajectory was partly formulated first by Schuchardt (1914), when he also claimed that 'Black English,' now identified as African American Vernacular English (AAVE) or Ebonics, had gone through all the evolutionary stages: pidgin > creole > post-creole. One of the clearest statements of the position is to be found in Bloomfield (1933, p. 474): "when the jargon [which seems to have meant 'pidgin' to him] has become the only language of the subject group, it is a *creolized language*." Hall (1962, 1966) espoused this position, associating the vernacular function of creoles with nativization. Since then, creoles have been defined inaccurately as 'nativized pidgins,' i.e., pidgins that have acquired native speakers and have therefore expanded both their structures and functions (owing to their usage as a vernacular) and have stabilized. In fact, Hall (1966) alternates nativization with indigenization as becoming indigenous to the territory. He also introduced the pidgin-creole 'life-cycle' to which DeCamp (1971) added a 'post-creole' stage, whereby a creole could shed off its 'creole features' (misnomer for features associated with, or typically attested in, creoles lexified by European languages (none of them is exclusive to creoles)), precisely what Schuchardt (1914) thought had happened to AAVE.

The first creolist to have disputed the above evolutionary scenario is Alleyne (1971). As noted above, he argues that fossilized inflectional morphology in Haitian Creole (HC) and the like suggests that the European colonists did not communicate with the Africans in foreigner or baby talk (see below). Supporting this position, Chaudenson (1979ff) argues that plantation communities were preceded by homesteads on which mesolectal approximations of European lexifiers, rather than pidgins, were spoken by earlier slaves. This scenario is supported by the economic history of the relevant territories, as plantations typically took a long time to develop and land-owning families often took generations before accumulating enough capital to shift from a small farm to a large plantation and to gradually buy more and more slaves to work on it. Also, like some economic historians, Berlin (1998) observes that, in North American colonies, Black Creoles spoke the lexifier fluently. It also appears from ads on runaway slaves in English North American colonies that bad or poor English is typically associated with slaves imported as adults from Africa who had arrived recently. In addition, diachronic evidence of creoles suggests that the basilects developed during the peak growth of plantations (in the eighteenth century for most colonies!), when infant mortality was high, life expectancy was short, the plantation populations increased primarily by massive importation of slave laborers, and the proportion of fluent speakers of the earlier colonial varieties kept decreasing (Baker and Corne, 1986; Chaudenson, 1992ff, Mufwene, 2001).

The life-cycle model claims that as a creole continues to coexist with its lexifier, the latter exerts pressure on it to shed some of its 'creole features.' Thus, as claimed by Schuchardt (1914), AAVE would have evolved structurally closer to North American White English than Saramaccan putatively because of increased interactions of African Americans with White Americans since the abolition of slavery. Schuchardt did not factor in the influence that Portuguese exerted on the emergence of Saramaccan's structure, the fact that the substrate populations did not consist of identical proportions of speakers of the same African languages, nor the fact that the demographic disproportions where AAVE emerged, on the cotton and tobacco plantations, were in favor of the European populations, and racial segregation within the relevant North American populations started in the late nineteenth century, as opposed to the late seventeenth or early eighteenth century on the Surinamese plantations.

Jespersen (1921) and Bloomfield (1933) anticipated DeCamp (1971), Bickerton (1973), and Rickford (1987) in invoking 'decreolization' ('loss of "creole" features') – what should more accurately be called 'debasilectalization' (loss of basilectal features; alternative to and more accurate term than *decreolization*) – to account for speech continua in creole communities. Alleyne's (1980) position that social speech continua (consisting of a basilect, a mesolect, and an acrolect) and geographical continua (owing to the fact that creoles' structures have never been identical from Surinam to the United States) is consistent with the history of colonization. (The terms were coined by William Stewart (1965) with the following meanings: *basilect* 'the variety whose structures differ the most from the local standard variety of the lexifier', *acrolect* 'the local standard variety' (often misidentified as the lexifier, which was nonstandard instead), *mesolect* 'the broad range of intermediate varieties between the former two.' There arises of course the logical question of whether such continua should be considered unique to creole-speaking territories.) The population

structures were not identical from one colony to another and not every individual learned the target colonial language from identical speakers or was equally apt at second-language learning. Even within the same colony, such as Jamaica, the situation varied according to whether one lived on a small farm (where there was no segregation), on a large plantation (which was segregated), or in the city (which was not rigidly segregated, Dunn, 1972). Around the Atlantic and in the Indian Ocean, no creole emerged in the city; it was brought there after the abolition of slavery, when many former slaves refused to continue working on the plantations, were evicted from their cabins, and migrated to poor or working class neighborhoods in the emergent cities.

Just the opposite development occurred in Hawaii, where creole evolved in the city (where the Asian populations were more mixed) rather than on the plantations (where the Asian contract laborers were ethnically segregated, lived among themselves, received instructions for work from the overseer, who was their interpreter, and hardly felt the pressure to shift to English as their vernacular). (Unlike the descendants of Africans around the Atlantic and in the Indian Ocean, Asians in Hawaii have not lost their traditional ethnic identities as Chinese (Cantonese, Hokkien, etc.), Japanese, Korean, Filipino, etc. This ecological difference says a lot about the conditions of vernacular usage, which fostered the emergence of creoles.) In the United States, Gullah, which is structurally closer to North American English varieties than Jamaican Creole, emerged on the rice fields, which were demographically smaller than large sugar cane plantations of the Caribbean colonies. On the other hand, AAVE is structurally similar to American White Southern English, with which it shares ancestry on the cotton and tobacco plantations. Bajan (Barbadian Creole) is less divergent from the Caribbean English acrolect than Jamaican Patwa, simply because the island is smaller, had more indentured servants, and the African demographic majority over the European population was not as high as in Jamaica.

DeCamp (1971) did not factor in the above historical facts when he characterized language variation in Jamaica as a 'post-creole continuum.' As a matter of fact he adduced no diachronic evidence in his invocation of 'decreolization' to account for the continuum. He just documented the variation from the basilect to the acrolect so adequately that he could posit an informative 'implicational scale' in the way the variants can be used. However, this need not be correlated with how the language had evolved ultimately from its lexifier.

On the other hand, there is no particular reason why the structures of a creole should be expected to be monolithic. If a variety is characterized as creole just because of the particular sociohistorical ecology of its development (see below), rather than because of its structural peculiarities, it cannot stop being a creole even after some of the features have changed. Besides, basilectal and mesolectal features continue to coexist in these communities, suggesting that Creole has not died yet. Lalla and D'Costa (1990) present copious data against debasilectalization in Caribbean English creoles (CEC), just as Mufwene (1994) adduces linguistic and nonlinguistic arguments against the same process in Gullah. Although Rickford and Handler (1994) show that Barbados may have had a basilect comparable to that Jamaican Creole in the late eighteenth century, no evidence of such debasilectalization (different from the change without loss of the basilect documented by Rickford, 1987 regarding Guyanese Creole) has been documented about any other place. How the basilect may be claimed to have been lost in Barbados but not elsewhere in the Caribbean calls for an explanation. Winford (1997) offers an account of why Creole emerged not only later but not identically in Trinidad and Guyana. Only the latter has a basilect comparable to that of the Jamaica.

Are Creoles Separate Languages from Their Lexifiers?

Another contentious issue about creoles is the common stipulation by linguists that creoles are separate languages from their lexifiers and related excolonial varieties spoken by descendants of Europeans. Thus, the nonstandard French varieties spoken in Quebec and Louisiana, as well as on the Caribbean islands of St. Barths and St. Thomas, are considered dialects of French rather than creoles. Likewise New World nonstandard varieties of Spanish and Portuguese are not considered creoles (with the exception of Palenquero, spoken by a population of primarily African descent!), despite structural similarities that they exhibit with creoles of the same lexifiers, such as São Tomense, Principense (both spoken in the Bight of Biafra), Cape Verdiano Crioulo for Portuguese.

Interestingly, contact-based varieties spoken by descendants of Europeans or populations in which people of European descent are the majority are not considered as creoles. AAVE is not because, as noted above, it shares its origins with American (White) Southern English. Gullah, spoken by a majority-Black population has been stipulated to be a creole (its speakers think Creole is spoken only in Louisiana, which as has also produced 'creole cuisine'!), but Amish English is not, although it is nonstandard and spoken by descendants of people that are primarily of non-English, German-speaking Swiss descent. Ignoring Hjelmslev's (1938) and Posner's (1985) position that creoles are new dialects of European languages, creolists have adopted uncritically this socially based naming tradition in former European settlement colonies, identifying as creoles those varieties of European languages that have been appropriated as vernaculars by non-European majorities.

There is yet no yardstick for measuring structural divergence from the lexifier, nor was the latter the same in every contact setting. Contact of dialects and/or languages was indeed a factor in all colonial settings, especially in places such as the United States and Australia, where descendants of the English constitute a small proportion of the people of European descent. Granted that the varieties spoken by these colonial populations are not as divergent as those labeled creoles in the same nations, what are the particular factors within or other than contact that justify the distinction in ways different from those that account for variation among creoles? Could the fact that majority Europeans of non-English descent shifted to English after its formative phases

in the colonies explain why the influence of the new speakers has remained limited (Mufwene, 2009a)?

Do Creoles Form a Typological or Genetic Class of Their Own?

It has also been claimed that creoles have more or less the same structural design (Bickerton, 1981, 1984; Markey, 1982). This position is as disputable as the counterclaim that they are more similar in the sociohistorical ecologies of their developments (Mufwene, 1986a) or even the more recent claim that there are creole prototypes from which others deviate in various ways (Thomason, 1997; McWhorter, 1998). (According to John H. McWhorter, a creole that exhibits the most "creole features," especially one that also has no tones and no derivational or inflectional affixes. This is different from the notion of "epistemic prototype" used in this article for the creoles (of the Atlantic and Indian Ocean, all lexified by Western European languages) that linguists first investigated and have informed the scholarship on creoles and pidgins. The very fact of resorting to a handful of prototypes for the general creole structural category suggests that the vast majority of them do not share the putative set of defining features, hence that the features cannot be used to single them out as a unique type of language. (Typological classifications are typically of the classical-category kind, with no exceptions, rather than of the prototype-category type, relying on family resemblance with a tiny core of best exemplars!) It is tantamount to saying that some ergative or SOV languages belong less in the lot than others after claiming that they all fit in the same category. As underscored by Meyerhoff (2009), many of the same features and combinations thereof are attested in languages that are not considered as creoles.

On the other hand, variation in the structural features of creoles (lexified by the same language) is correlated with variation in the linguistic and sociohistorical ecologies of their developments (Mufwene, 1997, 2001). The notion of 'ecology' includes, among other things, the nature of the lexifier, structural features of the substrate languages, changes in the ethnolinguistic makeups of the populations that came in contact, the kinds of interactions between speakers of the lexifier and those of other languages, and rates and modes of population growth.

It has also been claimed that creoles are structurally simpler than other languages. In the lead of this claim are McWhorter (1998, 2001), which have generated numerous responses in support or against the position. Leading the latter are DeGraff (2001, 2005, 2009), which also raise the question of how variably complexity is conceived of in the first place. This raises also the question of whether it is even possible to address the question fruitfully without presupposing a bias toward what the architecture of language is expected to be like (Meyerhoff, 2009; Mufwene, 2009b). Generally lacking from claims of the reduction of complexity in creoles are considerations of the interpretation principles that underlie the putatively simpler structures or the interactions between rules and between modules. It is also noteworthy that creoles lexified by European languages lack tones (one of the criteria stipulated by McWhorter, 1998), because their lexifiers are nontonal. It is not obvious that they lack derivations, as made obvious by DeGraff (2001). Regarding inflections, they seem to have followed the tendency observable in the evolution of the same European languages, as is made obvious in Chaudenson (2001, 2003).

To date the best-known creoles have been lexified by English, French, Portuguese, and Dutch. Those of the Atlantic and Indian Ocean are, along with Hawaiian Creole, those that have informed most theorizing on the development of creoles, which I identify as the epistemic prototypes. The reader should remember that the colonization of Hawaii started after the abolition of the slave trade and the population structure on Hawaiian plantations was unlike that instituted around the Atlantic and in the Indian Ocean, where pressure to operate in the European colonial language was experienced since the homestead phase of colonization. Whoever wishes to generalize over the formation of creoles should beware of extrapolating too hastily from one part of the world to the other (Mufwene, 2005, 2008).

While the terms 'creole' and 'creolization' have been applied often uncritically to various contact-induced language varieties, several distinctions, which are not clearly articulated have also been proposed, for instance, between pidgin, creole, koiné, semicreole, intertwined varieties, foreign workers' varieties of European languages (e.g., Gastarbeiter Deutsch), and, we may add, indigenized varieties of European languages (e.g., Nigerian and Singaporean Englishes). The denotations and importance of these terms deserve reexamining (Holm, 1988, 2004; Arends et al., 1995; Mufwene, 1997, 2005; Bakker, 2009).

Confusing expanded pidgins such as Tok Pisin with creoles (Thomason, 2001; cf Siegel, 2008) depends conceptually on whether one subscribes to the position that creoles are nativized pidgins. Discussions that lump them together are informative in showing the extent to which different evolutionary trajectories can nonetheless produce similar structural outcomes. On the other hand, the question arises of whether vernacularization (not to be confused with urbanization, *pace* Bakker, 2009), rather than nativization, is not a more critical factor driving the structural expansion of pidgins into expanded pidgins and keeping creoles from simplifying their morphosyntax to the same extent as pidgins.

Equally problematic is the unrestrained extension of the term 'creole' to a number of 'contact languages' associated indeed with (European) colonization but have not been lexified by European languages or associated with Creole people, based on the disputable assumption that they started as pidgins and have been nativized. Examples include Kikongo-Kituba, Lingala, Sango, and Kinubi in Africa, as well as Sri Lanka Malay, Bazaar Malay, and Ambonese Malay in Asia.

Creole 'Genesis'

The central question here is: how did creoles emerge? The following hypotheses are the major ones competing

today: the substrate, the superstrate, and the universalist hypotheses.

Substratist positions are historically related to the 'baby talk hypothesis,' which can be traced back to late nineteenth-century French creolists: Bertrand-Bocandé (1849), Baissac (1880), Adam (1883), and Vinson (1882). According to them, the languages previously spoken by the Africans enslaved on New World and Indian Ocean plantations were the primary reason why the European lexifiers, which they appropriated, were restructured into creoles. These early creolists assumed African languages to be 'primitive,' 'instinctive,' in 'natural' state, and simpler than the 'cultivated' European languages with which they came in contact. Creoles' systems were considered to be reflections of those of non-European languages, which allegedly reflected the mental inferiority of those who produced and spoke them. The African slaves were thus considered as incapable of learning the putatively more evolved structures of the European languages. The 'baby-talk' connection is that, in order to be understood, the Europeans supposedly had to speak to the Africans like to babies. More or less the same idea is to be found in the 'foreigner talk' hypothesis, according to which Europeans reproduced the non-Europeans' inaccurate approximations of their languages.

The revival of the substrate hypothesis (without its racist component) has been attributed to Sylvain (1936). Although she recognizes significant influence from French dialects, she concluded her book, surprisingly, with the statement that Haitian Creole is Ewe spoken with a French vocabulary. Over two decades later, Turner (1949), disputing American dialectologists' claim that there was virtually no trace of African languages in 'Black English,' highlighted some morphosyntactic similarities between 'the Gullah dialect' and some West-African (especially Kwa) languages. He then concluded that "Gullah is indebted to African sources" (p. 254), which stimulated more research on African substrate influence on African-American English (e.g., Dillard, 1972) and on CECs (e.g., Alleyne, 1980).

Mufwene (1990, 2010) identifies three main schools of the substrate hypothesis today. The first, led by Alleyne (1980, 1996) and Holm (1988), is closer to Turner's approach and is marked by what is also its main weakness: invocation of influence from diverse African languages without explaining what kinds of selection principles account for this seemingly random invocation of sources. This criticism is not *ipso facto* an invalidation of substrate influence. It is both a call for a more principled account, one that articulates the particular ecological factors that appear to have favored various individual influences (thus legitimating what was dubbed the 'Cafeteria Principle'), and a reminder that the nature of such influence must be reassessed.

The second school, identified by its practitioners as the relexification hypothesis (RH), is fully articulated by Lefebvre (1998), who argues that HC consists largely of French lexical entries spoken with the grammar of languages of the Ewe-Fon (or Fongbe) group. Extended to other creoles, the position, has been repeated in some of the contributions to Lefebvre et al. (2006), though some others (see especially Aboh, 2006; Siegel, 2006) dispute it, and almost all of those to Lefebvre (2011) are more cautious. Objections to this phylogenetic hypothesis include the following: (1) RH's 'comparative' approach has not taken into account several features that HC (also) shares with nonstandard French; (2) RH downplays features that HC shares also with several other African languages, which were represented in Haiti during the critical stages of its development, thus it is not obvious why the exclusive focus on the Ewe-Fon languages; (3) studies of naturalistic second language acquisition provide no evidence in support of RH, even if the emergence of creoles could at all be associated exclusively with adult L2-learners (Chaudenson, 2001, 2003); and (4) RH does not account for those cases where HC has selected structural options, which are not consistent with those of Ewe-Fon. Moreover, relexificationists assume, disputably, that languages of the Ewe-Fon group are structurally identical in all respects and that no competition of influence was involved among them. (The competition here refers to unequal ranking by speakers of variants that serve more or less the same function in a system (in a particular ecology or setting of interactions). Selection is the process that resolves the competition, in favoring a particular variant.) The most elaborate critique of RH is DeGraff (2002), which is complemented by various refined analyses of hybridized structures in Haitian by Aboh (2006, 2009, 2015, among many others). For contrary evidence from other creole-like languages (in the sense of this article), see especially Siegel (2006).

The least disputed version of the substrate hypothesis is Keesing's (1988), which shows that substrate languages may impose their structural features almost intact on the new, contact-induced varieties if they are typologically homogeneous, with most of them sharing the relevant features. Thus Melanesian pidgins are like (most of) their substrates in having DUAL/PLURAL and INCLUSIVE/EXCLUSIVE distinctions and in having a transitive marker on the verb. Sankoff and Brown (1976) had shown similar influence with the bracketing of relative clauses with *ia*, as does Sankoff (1993) with the focus marker in Melanesian pidgins and Jourdan (2009) with prepositional-verb markers in Solomon Island Pidgin. Keesing argued that even the subject-object-verb order of Melanesian pidgins' sentences reflects the order of the argument affixes in the verb complex, which is often used elliptically, although the dominant order of free arguments is verb-subject-object in the relevant substrate languages.

This evolution is facilitated by what Singler (1988) calls 'homogeneity of the substrate' (argued for earlier in Mufwene, 1986b), if it is not downright its consequence. However, the pidgins have not inherited all the peculiarities of Melanesian languages. For instance, they do not have their VSO major constituent order, nor do they have much of a numeral classifying system in the combination of *pela* with quantifiers. For an extensive discussion of substrate influence in Atlantic and Indian Ocean creoles, see Muysken and Smith (1986) and Mufwene (1993). For similar discussions about creoles and the like in the Pacific, see Lefebvre et al. (2006) and Lefebvre (2011).

Competing with the above genetic views has been the dialectologist, or superstrate, hypothesis, according to which the primary, if not the exclusive, sources of creoles' structural features are nonstandard varieties of their lexifiers. Regarding African American English, Krapp (1924) and Kurath (1928), for example, claimed that this variety was an archaic retention of the nonstandard speech of low-class European colonists with whom the African slaves had been in contact. According to these dialectologists, African substrate influence was limited to some isolated lexical items such as *goober* 'peanut', *gumbo*, and *okra*. Although substrate influence need not be dismissed offhand (see below), the position is worth considering critically, especially if one factors in the presence of nonnative speakers of English among the European indentured servants with whom the slaves interacted regularly, especially during the early stages of colonization. This is even more significant in the case of Surinam, where the Dutch colonists adopted English as the language of communication with their slaves.

It would take until McDavid (1950) and McDavid and McDavid (1951) before dialectologists made allowance for some African grammatical contributions to AAE. Otherwise, D'Eloia (1973) and Schneider (1989) invoke several dialectal English models to rebut Dillard's (1972) thesis that AAVE developed from an erstwhile West-African Pidgin English (WAPE) brought over by slaves. Had they known then the language of the slave trade was probably Portuguese, they could have pointed out that WAPE varieties probably emerged later than AAE in the first place. The scant evidence presented by Dillard dates from the early eighteenth century and is closer to nonstandard English than to Pidgin English. Hancock's (1986) 'Guinea Coast Creole English,' spoken primarily in the mixed households of English factors and indigenous women need not have been as widespread as he claims and certainly not a pidgin, since the interactions in these settings were not sporadic.

Since the late 1980s, Shana Poplack and her associates have shown that AAVE shares many features with white nonstandard vernaculars in North America and England, thus it has not developed from an erstwhile creole (Poplack and Tagliamonte, 2001; Poplack, 2000). Because some of the same features are also attested in creoles (Rickford, 1998), we come back to the question of whether many, if not most, features of creoles did not originate in their lexifiers in the first place. The other question is also whether African substrate influence on AAVE must of necessity have come through creoles. History suggests that Gullah and AAVE evolved in geographic complementary distribution and apparently concurrently. During the eighteenth century, when the plantation economy was the most prosperous in English North America, only 15% of the slaves were imported from the Caribbean (Rawley, 1991). The oldest CECs would be just emerging then.

Regarding French creoles, the dialectologist position was first defended by Faine (1937), according to whom HC was essentially Norman French. This position was espoused later by Hall (1958), who argues that "the 'basic' relationship of Creole is with seventeenth-century French, with heavy carry-overs or survivals of African linguistic structure (on a more superficial structural level) from the previous language(s) of the earliest speakers of Negro Pidgin French [which can be situated nowhere in colonial history!]; its 'lexical' relationship is with nineteenth- and twentieth-century French" (1958, p. 372). Chaudenson (1989ff) is more accommodating to substrate influence as a factor that accounts for the more extensive structural divergence of creoles from their lexifiers compared to their noncreole colonial kin.

Chaudenson's allowance for substrate influence is fleshed out especially by Corne (1999), who articulates the most explicitly how feature selection can be driven by congruence, even if only partial, between the languages in contact. Although, unlike Pacific pidgins, the Atlantic and Indian Ocean French creoles did not typically emerge in settings that satisfied Singler's (1988) 'homogeneity of the substrate' condition, partial structural congruence between their substrates and nonstandard French favored the selection of the particular features they have, for instance, in the domain of time reference. Aboh (2006ff) has carried this approach farther with detail analyses that show how structural traits can be hybridized in ways similar to biological gene recombination, more specifically with serial verb constructions and number delimitation. One must then determine whether such substrate influence, which does not boil down to mere introduction of features from substrate languages (identified by Allsopp, 1977 as 'apports'), was facilitated by the numerical proportion of speakers of the relevant languages and/or by the time of the insertion of these in the linguistic feature pool. See Singler (1996, 2009) for such considerations regarding HC.

The 'universalist hypotheses,' which stood as strong contenders to substrate hypotheses in the 1980s and 1990s, have forerunners in the nineteenth century. For instance, Adolfo Coelho (1880–1886) partly anticipated Bickerton's (1981ff) 'language bioprogram hypothesis' in stating that creoles "owe their origin to the operation of psychological or physiological laws that are everywhere the same, and not to the influence of the former languages of the people among whom these dialects are found." Bickerton pushed things further in claiming that children, not adults, made creoles by fixing the parameters of these new language varieties to their unmarked, or default, settings as specified in Universal Grammar. To account for cross-creole structural differences, Bickerton (1984, p. 176–177) invokes a 'pidginization index' (PI) that includes the following factors: the proportion of the native to nonnative speakers during the initial stages of colonization, the duration of the early stage, the rate of increase of the slave population after that initial stage, the kind of social contacts between the native speakers of the lexifier and the learners, and whether or not the contact between the two groups continued after the formation of the new language variety. These factors, which one may recognize in Mufwene's ecological (1996ff) approach, were simply not anchored in the actual history of the colonization of the different creole-speaking territories.

Some nagging questions with Bickerton's position include the following: Do structures really support the claim that they were produced primarily by children (cf DeGraff, 1999a; Roberts, 1998)? Is his intuitively sound PI consistent with his creolization as abrupt pidgin-nativization

hypothesis (Mufwene, 1999)? Is the abrupt 'creolization' cum basilectalization hypothesis consistent with the social histories of the territories where classic creoles developed? How can we explain similarities between abrupt creoles and expanded pidgins when the stabilization and structural expansion of the latter is not necessarily associated with restructuring by children (Meyerhoff, 2009), *pace* some claims to be found in references such as Holm (1988) and Thomason (2001)? Is there convincing evidence for assuming that adult speech is less controlled by Universal Grammar than child language is? If so, how can we then account for similarities between abrupt 'creolization' and naturalistic second-language acquisition?

Not all creolists who have invoked universalist explanations have made children critical to the emergence of creoles. For instance, Sankoff (1979) and Mühlhäusler (1981) make allowance for Universal Grammar to operate in adults, too.

Few creolists nowadays subscribe to one exclusive genetic account, as evidenced by the contributions to Mufwene (1993) and implicitly those to Lefebvre (2011). The 'complementary hypothesis' (Baker and Corne 1986; Corne (1999), DeGraff (2009), Hancock 1986; and Mufwene 1986b, 2001) seems to be an adequate alternative, provided we can articulate the ecological conditions under which the competing influences (between the substrate and lexifier languages and within each group) may converge or prevail upon each other. This position was well anticipated by Schuchardt (1909, 1914) in his accounts of the genesis of the Mediterranean Lingua Franca and of Saramaccan. More and more research is now underway uncovering the sociohistorical conditions under which different creoles have developed, for instance, Arends (1989ff), Baker (1982ff), Chaudenson (1979ff), Corne (1999), Mufwene (2001ff), and Arends (1995). Aboh's (2006ff) hypothesis of hybridization of features even within properties of lexical items is an improvement not only over Corne's (1999) congruence model but also on Mufwene's (2001ff) ecology-specific restructuring.

In connection with the above discussion, note that the traditional claim that creoles emerged within one generation, thus abruptly, from a pidgin ancestor, has increasingly been questioned by, e.g., Chaudenson (1979ff), Arends (1986ff), Singler (1996ff), and Mufwene (1996ff). Baker (1995) provides part of the evidence in the context of pidgins, pointing out that their features did not all emerge at the same time. The strongest evidence lies in the fact that the oldest documentary evidence shows more similarity to European nonstandard varieties than the later or present-day materials. The evolutionary scenario is also consistent with the gradual way in which plantation colonies evolved, having started from homestead settings settled by small integrated groups in which the slaves were in the minority. Shortage of money also made it difficult to import more slaves and the colonial populations then grew more by birth than by importation (Mufwene, 2001ff).

Still, the future of research on the development of creoles has problems to overcome. To date, knowledge of the nonstandard lexifiers spoken by the European colonists remains limited, though more research is now underway and much of the scholarship on the dialectology of the European lexifiers is becoming handy. There are few comprehensive and integrated descriptions of creoles' structures, especially from a diachronic perspective, which makes it difficult to determine globally how the competing influences interacted among themselves and how the features selected from diverse sources became integrated into new systems. Few structural facts have been correlated with the conclusions suggested by the sociohistorical backgrounds of individual creoles, especially in studies that make strong claims for the typological singularity of creoles. Other issues remain up in the air, for instance, regarding the markedness model that is the most adequate to account for the selection of features into creoles' systems. Can there really be an ecology-independent, universal scale of markedness that can account for the selection of particular features into the structures of particular creoles or pidgins? For developmental issues on PCs, the following edited collections are highly recommended: Hymes (1971), Valdman (1977), Hill (1979), Muysken and Smith (1986), Mufwene (1993), Arends et al. (1995), DeGraff (1999b), Lefebvre et al. (2006), Ansaldo et al. (2007), Kouwenberg and Singler (2009), Lefebvre (2011), and several edited volumes of the Creole Language Library (Benjamins). One should of course also check *Amsterdam Creole Studies*, the *Journal of Pidgin and Creole Languages*, and *Etudes Créoles*. Several issues of *Pacific Linguistics* and *Te Reo* also include publications on Melanesian pidgins.

Creolistics and General Linguistics

There is much more literature on the emergence, sociology, and morphosyntax of PCs than on their phonologies, semantics, and pragmatics. Faraclas and Klein (2009) are exceptional in devoting almost half the volume to phonetics/phonology. More unusual is Bhatt and Plag (2007), devoted entirely to prosodic features of creoles and other 'contact languages.' The volume of publications is also now increasing on ethnographic and other social aspects of creoles and pidgins, with a special section devoted to such topics in Kouwenberg and Singler (2009).

With the exception of time reference (e.g., Singler, 1990; Michaelis, 1993; Schlupp, 1997) and noun phrase structure and nominal number (for references, see Tagliamonte and Poplack, 1993; Baptista and Gueron, 2007), studies in semantics and pragmatics are in the minority. On the other hand, the development of quantitative sociolinguistics owes a great deal to research on AAE since the mid-1960s (see, e.g., Labov, 1972; Rickford, 1999) and on CECs (e.g., Rickford, 1987). Numerous publications in *American Speech*, *Language in Society*, and *Language Variation and Change* reflect this. There are also several monographs on creolistics today that provide an overview of the scholarship on creoles and pidgins today. They include Romaine (1988), Holm (1988), Manessy (1994), Arends et al. (1995), Mühlhäusler (1986), Sebba (1997), Corne (1999), Chaudenson (2001, 2003), and Siegel (2008). They vary in geographical areas of focus, adequacy, and kinds of lexifiers.

Studies of the morphosyntax of creoles have yet to inform general linguistics beyond the subject matters of time reference, serial verb constructions, and grammaticization. For

instance, studies of lectal continua (e.g., Escure, 1997) have had this potential, but little has been done by creolists to show how their findings may apply to other languages. The nonmonolithic nature of 'mesolectal structures' as the intermediate sociological zone where acrolectal and basilectal features naturally mix into one system allowing more variation should have informed general linguistics against the fallacy of monolithic grammatical systems (Mufwene, 1992). (This is a different position from Labov's (1998) 'coexistent systems' hypothesis, which suggests that each of the systems may still be monolithic.) More work could have been done to eradicate the misconception that continua are typical of creole-speaking communities only; these phenomena can be observed in any population where the standard/nonstandard distinction applies and colloquial speech is accepted as normal. Based on observations such as Rickford (1990) that mesolectal speech is the norm in creole-speaking communities, more work could have been done about whether the notions BASILECT and ACROLECT are not in fact elusive constructs of convenience that are associated with analyses intended to amplify structural differences between creoles and the European languages they have evolved and diverged from.

Likewise, the debate on 'creole genesis' could have informed genetic/historical linguistics on the relevance of varying external-ecology conditions to the actuation question , to language change and speciation, and even to language vitality (Mufwene, 2001, 2005, 2008). (The actuation question is that of identifying the ecological motivation of change, i.e., the particular factors outside language that triggered a particular change at a particular point in time, owing to particular interactional dynamics.)

Note also that a concomitant of the emergence of creoles around the Atlantic and in the Indian Oceans was the loss of heritage languages among the (descendants of) the enslaved Africans. The fact that language loss as a concomitant of language shift was experienced only later by European colonists who had different heritage languages than the dominant one may very well account for why the divergence of other colonial offspring of the same European languages was not as extensive among descendants of most Europeans. It appears that they were acculturated relatively late and did not participate as early as the slaves and European indentured servants in shaping the new colonial vernaculars (Mufwene, 2009a). Their gradual assimilation to the population that had been speaking the dominant European language as a heritage vernacular is another important factor that filtered out much of the adstrate element that had once justified speaking of, for instance, German and Italian Englishes in the United States.

Although lack of consensus among creolists may be invoked as a general reason for this failure to influence general linguistics, alarming indifference from theoretical linguists, especially those engaged in theories of typology and universals, is a more important reason. Granted, the recent publication of the 'Atlas of Pidgins and Creoles' (Michaelis et al., 2013) can make some difference; the question remains of whether the typological values assigned to characteristics of some creoles are inspired from within (which would be more promising) or from without (which is no more than intellectual colonization).

Consensus cannot be expected of creolistics any more than it can of other subfields of linguistics or any other scientific discipline. Nonetheless, in the broader context of language contact (including second-language acquisition), studies of especially the emergence of creoles have been inspiring. For instance, Thomason and Kaufman (1988) is widely cited in studies of indigenized Englishes. Schumann (1978) and Andersen (1983) were an important step in consolidating common interests between second-language acquisition and the emergence of creoles. The journal *Studies in Second Language Acquisition* has sometimes featured lead articles on creoles and SLA. Lefebvre et al. (2006) is indicative of the kind of mutual stimulation that can obtain between creolistics and the scholarship on SLA (Mufwene, 2010). More cross-fertilization might be expected between studies of creole genesis and those of (child) language development (DeGraff, 1999b), as among diverse subfields of linguistics.

No less significant is the contribution that creolists have made to the scholarship on grammaticization, owing largely to the reception that the leading practitioner, Bernd Heine, himself one of the first students of language contact in Africa, has extended to such research. The first milestones are to be found in Bruyn (1995) and Baker and Syea (1996).

There is also hope in the recent growing number of publications addressing the question of whether creoles are simpler than other natural languages, including Dahl (2004), Gil (2007), Faraclas and Klein (2009), DeGraff (2001, 2009), Aboh and Smith (2009), McWhorter (2001, 2012), and Mufwene (2009b, 2013). Creole studies are definitely moving away from the periphery of the linguistics profession. They have also claimed center stage in research on the phylogenetic emergence of language (Bickerton, 1990, 1995, 2010; Botha, 2006; Mufwene, 2008, 2010; Hurford, 2012), competing with the scholarship on gestures (McNeill, 2012) and sign language. Perhaps the time has finally come when creoles can influence the way linguists and other scholars study language more conspicuously.

Abstract

Pilgrimage involves the movement of the traveler or group of travelers away from home, usually with a specific, sacred goal in mind. The institution is of interest within the social sciences because it can entail the cross-cutting of conventional geographical, cultural, and religious boundaries. Older theories of pilgrimage stressed its capacity to encourage moral regeneration and the social unification of otherwise dispersed populations. Many anthropologists have compared pilgrimage with rites of passage within tribal peoples and argued that it allows people to strip away their normal, everyday identities during the restricted space and time of the journey. More recent work in the social sciences emphasizes the continuity between pilgrimage activities and the social, religious, and political fragmentation of daily life. Scholars note that pilgrimage has maintained or even increased its popularity even as the boundaries between religiously motivated travel and mass tourism have sometimes become blurred. Contemporary pilgrimage has therefore been examined in the broader context of the expanded mobility of people, cultures, and objects that is evident in many parts of the world.

Pilgrimage involves the movement of a traveler or group of travelers away from home, usually with a specific, sacred goal in mind. In most cases, the term implies a journey to a place that has been sanctified by the presence or actions of a divinity or holy figure. Certain variations on this pattern are possible. Pilgrims sometimes wander continuously without a fixed destination, or the journey may be considered to occur in a purely metaphorical sense, involving spiritual development and transformation within the person. This article focuses, however, on the most common understanding of pilgrimage: literal movement across space that may also result in the crossing of conventional cultural, social, and religious boundaries.

Themes in the Study of Pilgrimage

Social scientific studies of pilgrimage were relatively sparse until the 1970s, although in the 1950s Eric Wolf had published a short but influential article on pilgrimage to the Virgin of Guadalupe in Mexico (Wolf, 1958). Since the early 1970s, research has expanded and covered all of the world religions. Such academic engagement reflects a continuing and even increasing interest in pilgrimage that has become evident among participants who have better access than ever before to safe and effective modes of travel.

Many earlier studies adopted Durkheimian, functionalist perspectives in analyzing the significance and effects of pilgrimage. In other words, they interpreted the process of traveling to and gathering at a sacred place as providing ritualized opportunities for social unification and moral regeneration within populations that were normally widely dispersed. For instance, Wolf (1958) argued that the shrine of the Virgin of Guadalupe in Mexico City represented a dominant symbol for the whole nation, condensing various historical, mythical, and cultural themes and focusing them on the activity of pilgrimage to a single place.

The most influential social scientific approach to the subject has come from the anthropologist Victor Turner (see, for instance, Turner and Turner, 1978). He notes that, after an original founding event such as a vision, journey, or martyrdom, pilgrimages most frequently involve the gradual organization and routinization of the sacred journey. More speculatively, Turner argues that pilgrimage in the world religions shares certain characteristics with rites of passage in tribal societies. In both forms of ritual, the person is removed from the space and time of the everyday social environment and undergoes an emotionally and physically testing experience that can have lasting effects on perceptions of self-identity. Pilgrims thus enter the realm of what Turner calls social antistructure or *communitas*. He means by these terms that pilgrimage can involve the stripping away of everyday social statuses among participants, resulting in liberation from conformity to conventional norms and hierarchies. Pilgrims ideally cultivate direct and egalitarian bonds of comradeship during the temporary, set-apart time of their journey and dwelling at a shrine. *Communitas* therefore has the potential to contain an element of social critique since it puts the taken-for-granted quality of conventional institutions in question. Representatives of orthodoxy in many of the salvation religions often feel ambivalent towards pilgrimage and attempt either to suppress or control its tendencies to foment lay frustration with religious hierarchies.

Turner notes further that pilgrimage is frequently associated with images of death and rebirth, mirroring the symbolic destruction and reconstruction of the religious traveler's identity. For instance, many who go on the major pilgrimage (or *hajj*) to Mecca will choose to be buried in the white robes they wore on the pilgrimage. It is believed that these people will thus present themselves at the Last Judgment in the garb appropriate to a rejection of worldly, profane actions.

Turner's work has proved to be so significant partly because it appears to provide a vocabulary and theoretical framework that can be generalized and applied to varied cultural contexts. However, numerous subsequent works have criticized aspects of his thesis that pilgrimage is inherently antistructural in form

and significance. Authors have pointed out that such a paradigm is possibly more reflective of a Christian ideal of human fellowship than of social and political realities in religious systems in general. Many examples of pilgrimage appear actually to reinforce situations of conflict between participants. For instance, Messerschmidt and Sharma (1981) examine Hindu pilgrimage in Nepal and find that caste and class divisions are not transcended through common engagement in the ritual. They argue further that conventional Christian ideals of egalitarianism and homogeneity contradict certain Hindu assumptions concerning the inevitable persistence of religious hierarchy.

Powerful and widely cited criticisms of the Turnerian paradigm are contained in a book that is ostensibly devoted to studies of Christian pilgrimage but presents arguments that have much wider application. Eade and Sallnow (1991) characterize pilgrimage sites as ideal locations for contesting, rather than consolidating, the sacred among religious participants. As centers of power that can provide religious legitimation for political aspirations, shrines often present powerful incentives for a particular interest group to attempt to control the behavior and beliefs of religiously motivated visitors (the point is illustrated clearly by the politically charged and often violent history of Jerusalem). Pilgrimages, according to this view, provide the material and ideological focus for competing discourses and agendas, not only between sacred and secular authorities, but also between lay pilgrims and clerics, locals and incomers, members of different denominations, and so on. Sacred sites are described by Eade and Sallnow as the equivalent of empty symbolic vessels waiting to be filled by the possibly mutually contradictory assumptions of the various people who visit them. The authors also suggest that to regard pilgrimage as a unitary institution is highly problematic, even within a single religious system, since it can contain so many historically specific behaviors and meanings. They add, however, that Christian and perhaps other forms of pilgrimage can be conceptualized as involving a basic triad of 'person,' 'place,' and 'text.'

In fact, Turner did anticipate at least some of the later criticisms that have been leveled at his model of pilgrimage. He was aware of the potential for pilgrimage sites to be co-opted by political elites, the fragility of states of *communitas*, and the capacity of pilgrimage sites to encourage widely differing interpretations from pilgrims. However, the notion that pilgrimage should be seen as an arena for contestation as much as cooperation has proved popular in recent years. Its adoption by many scholars is not surprising since it resonates with contemporary social scientific perspectives that have been influenced by postmodern understandings of culture as unstable, fragmentary, and open to multiple appropriation.

A less controversial set of issues, discussed by Turner and others, is raised by the contention that pilgrimage can encourage participants to consider themselves part of translocal religious and cultural systems. Among Hindus, for instance, a sense of participation in a sacred geography that covers the whole of the Indian subcontinent can be cultivated by travel to shrines. Some devotees choose to circumambulate the entire country, visiting sacred spots along the way. Holy places themselves may be officially or unofficially ranked in importance, thus constituting an internally heterogeneous but widely dispersed framework of sites. Among Christians, Jerusalem (located within 'the Holy Land' itself) has often been regarded as the pre-eminent location for pilgrimage, containing as it does so many sites associated with biblical events. It is followed in importance by other locations of transnational importance, such as Rome or Compostela, and then by pilgrimage locations that have significance in national or more narrowly defined regional contexts.

Methods of Study

Pilgrimage raises unusual problems in relation to conventional social scientific methodologies. Any given site is located within a much wider political, economic, and religious framework that must be taken into account in analysis. As a religious practice, pilgrimage has often complemented (and incorporated) other translocal activities like trade, tourism, and exploration. Pilgrims themselves may move across geographical, social, and religious boundaries, so that the scholar is faced with a diffuse and literally shifting object of study.

Various methods can be used to encapsulate the most important aspects of the phenomenon. Pilgrims can be followed as they journey to a shrine (Gold, 1988; Frey, 1998). More commonly, a single pilgrimage center or shrine is focused upon, and the activities of various pilgrim groups observed as they pass through the sacred center (Dubisch, 1995). At a wider, macro level of analysis, whole systems of pilgrimage within a religious tradition may be studied (Turner and Turner, 1978), or comparisons made between pilgrimage systems in the various world religions (Coleman and Elsner, 1995).

The fact that pilgrimage sites tend to persist over time provides a good opportunity to combine historical with sociological interests (Turner and Turner, 1978), and much work in this area demonstrates the ways in which a given site can retain its identity as a sacred place despite the fact that it is appropriated by different and sometimes competing religious systems over perhaps hundreds of years. Guadalupe, for instance, provides a good example of a shrine that has probable pre-Christian as well as Christian roots. The mixture of religious associations increases its significance as a site whose symbolism and mythology can be invoked in current debates concerning the relationship between precolonial, colonial, and post-colonial identities in Mexico.

Future Themes of Research

Pilgrimage has the potential to be at the center of much future research that could be of importance to the social sciences in general. As a social phenomenon, it encourages the researcher to engage with some key theoretical debates in a variety of disciplines. The current popularity of pilgrimage as an activity raises the question of its significance for predictions of secularization and/or religious revitalization in various parts of the world. Some scholars have also speculated over the extent to which apparently secular activities such as going on holiday or visiting the graves of pop stars share the same structural

features as pilgrimage. Certainly, it seems likely that tourism and pilgrimage will become increasingly intertwined in many cultural contexts in the future, given the popularity and flexibility of both activities. In addition, pilgrimage studies are relevant to ongoing discussions of the significance of processes of globalization in the modern world. Studies of sacralized forms of travel, involving the transference of people, ideas, and objects across national borders, can complement other research that is concerned to understand how social, cultural, and political units are being transformed by developments in technologies of mass travel and communication. Furthermore, in a world that is characterized by the displacement of populations from traditional homelands, pilgrimage may emerge as an increasingly important institutional means through which to unite diasporic communities. Tweed (1997) has recently argued, for instance, that pilgrimage allows Cuban exiles in Florida to map the landscape and history of their country of birth on to a new environment. Finally, pilgrimage provides many possible avenues of research in the light of increased social scientific interest in the body and embodiment, ranging from a focus on beliefs in miraculous healing to analysis of forms of movement associated with travel to and around sacred shrines.

Abstract

Place is a foundational concept in human geography but is often regarded as synonymous with terms such as location, locale, region, space, territory, and landscape. It is important to illustrate the diverse ways in which place has been conceptualized through the evolving strands of humanist, phenomenological, radical (including Feminist, Marxist, and Postcolonial), and more recent posthumanist and nonrepresentational thought. This article provides an overview of the evolving theorization of place in geography, and reflects on how assemblage thinking may refine geographical conceptions of place.

Place is a foundational concept in human geography, but, when taken uncritically, is used interchangeably with terms of location, locale, region, space, territory, and landscape. Throughout the history of the discipline, place alongside space has provided the building blocks of geographical investigation, and continue to undergo theoretical refinement and debate. This article provides an overview of the evolving theorization of place in human geography, and reflects on how the concept of place might be developed through the notion of assemblage.

Place

The concept of place has played an important role throughout Western philosophy from Plato to the present (see Casey, 1997; Livingstone, 1992). For the most part place was thought of as an unproblematic category, viewed as a passive and empty container (McKeon, 1941) or a human-wrought occupation of preexisting, undifferentiated space. During the second half of the twentieth century, new philosophical approaches, coupled with the changing character of actual 'places' under globalization, brought new questions about ideas of 'place.' These developments can be seen in Agnew's (1987) three basic attributes of place. In its elementary meaning, place refers to 'location,' the 'where of something' in an absolute or relative sense (through agreed measures of latitude or longitude marks, or 5 km south from x). This conception underpinned the spatial science turn in the 1960s and the tenets of central place theory (Christaller, 1966), that considered towns and villages in terms of measurable properties and relative locations, and in doing so largely emptied places of subjective content. The new scientific method sought to replace the overly descriptive tendency that thus far characterized traditional regional geography and its chorological approach to collecting and classifying objective attributes about places (for instance, population size, natural resources, economic productivity) (see Hartshorne, 1959). The second of Agnew's aspect of place is 'locale,' which denotes the material things that structure social and cultural life (buildings, roads, rivers, marketplaces, signposts, for example). The third place-characteristic in Agnew's typology is 'sense of place,' the ways in which places are made meaningful through personal experience and through social mediations and constructions of place.

Humanistic Geography

Sense of place was a driving theme of humanistic geography during the 1970s. Geographers such as Yi-Fu Tuan, Anne Buttimer, Edward Relph, and David Seamon, dissatisfied with the lack of attention spatial science tradition gave to the meanings given to places, drew extensively on the phenomenology of Martin Heidegger and Maurice Merleau-Ponty (Tuan, 1971; Seamon, 1979; Heidegger, 1971; Merleau-Ponty, 1962). This approach sought to clarify the subjectivity of place experience, investigating individuals' attachments to particular places, and the symbolic role of places in fostering individual senses of belonging and dwelling in different cultures.

Place and Placelessness

The modernism of global capital flows, according to Relph (1976), erodes diversity and place distinctiveness by fabricating, uprooting, commodifying 'authentic' place-identities into internationally standardized shopping spaces, modernist planning, and tourist landscapes. This has culminated in scholars describing these homogenous sites as 'nonplaces' (Augé, 1995) or suffering a condition of 'placelessness' (Relph, 1976), where the loss of place diversity equates loss of 'authentic' cultures that produce senses of place. However, Harvey (1989), Entrikin (1991), and Massey (1997) warn of the reactionary impulse entailed in nostalgia for single and stable place-based attachments, and instead point to the opportunities to establish new progressive senses of place that are translocal in character (also see Featherstone et al., 2012). Despite these criticisms, the contributions of humanist geography fundamentally put place, sense of place, and placelessness at the center of a human geography agenda for years to come.

Radical Geography and the Cultural Turn

During the 1980s and 1990s the rise of new critical geographies (feminist, Marxist, postcolonial) and the 'cultural turn' saw place remain a key concern of geographers, albeit with a fundamental distinction. Place became understood less through the notion of the intentional human subject, instead scholars emphasized the role of power and politics, the ways

places are (re)made, and the role place plays in constituting social relationships in society-space (Cresswell, 2011). David Harvey (1973), who had been one of the first to challenge the positivist conception of space as an empty container or pregiven entity, developed a Marxist approach that emphasized how social practices and processes embedded in particular places and spaces are integral to the construction, and overthrowal, of capitalism. Doreen Massey (1984, 1991, 1993), also inspired by critical social theory, Feminism, and Marxist political-economy, set out a more *relational* conception of place through her analysis of political-economic and social processes that produce distinct urban and regional inequalities. Her work has been developed into at least four propositions for thinking about place (Cresswell, 2011). Firstly, place is not static but is produced through mobilities, flows, and differential power-relations. Place is a unique point of interaction within networks of social and economic relations. Secondly, place does not have boundaries, as in the superficial binary between local–global, rather place can be defined by its 'outside linkages.' Here global processes constitute 'local' senses of place and global economic flows are not disembodied ethereal entities but grounded in particular places, practices, and performances. Thirdly, places do not have single unique identities but place identity is a site of contestation by different groups in society, and by multiple, often contradictory, political-economic and social processes. Fourthly, and related, places are specific but are continually reproduced and open to contestation. This latter point led Massey and others to close the discursive distance between 'local' and 'general' struggles, emphasizing how place-based politics need not be parochial but can be networked into more egalitarian relations with global processes (Massey, 1991).

With the advent of the cultural turn in the 1990s (*see* Cultural Geography) the focus shifted from the humanistic accounts of 'sense of place' or Marxist perspectives on capitalist political-economy. Instead the politics of identity, difference and representation (Barnes and Duncan, 1992; Duncan and Ley, 1993) led geographers to develop conceptualizations of place that sought to unravel and challenge the spatial (re) production of inequalities along lines of gender, class, disability and sexuality. Cresswell (1996) examines how different identities are assigned to 'belong' to particular places. These contributions have led to politics of uncovering the explicit and implicit exclusions inherent in place construction, for instance, how homelessness is considered 'out of place' in rural areas through social constructions of the rural idyll (see Cloke et al., 2000). These discourses are reiteratively performed to produce dominant 'orderings of places.' Yet geographers working in a number of different arenas have emphasized the ways place-orderings are open for transgression and resistance. (Gill Valentine's, (1997; Skelton and Valentine, 1998) work on children's geographies and youth cultures illustrates how new meanings, senses of belonging, and experiences of place can be carved out from adult notions of public/private spaces. Geographical research on race has exposed how racisms are (re)produced through legislative spatial segregation (Smith, 1989), through dominant representations in film, television, music, and literature (Keith and Pile, 1993) as well as how places are socially constructed to maintain the 'neutrality' of 'white privilege' (Anderson, 1991; Kobayashi and Peake, 2000; Holloway, 2005). Feminist contributions (Rose, 1993) have challenged the humanistic assumptions of homeplace as stable and secure by highlighting constructions of homeplaces as sites of gendered labor and domestic violence (*see* Gender and Place). Geographers of sexuality have helped deconstruct everyday and institutional spaces of heteronormativity, and emphasize the role space plays in the construction and exclusion of a diverse range of homosexual and heterosexual performances, practices and identities. (Valentine, 1993; Hubbard, 2000). Geographies of religion has drawn attention to the ways places are made sacred (Yorgason and Della Dora, 2009), the construction of religious subjectivity (Hopkins et al 2013) and the ways meaning and experience of the 'divine' is mediated through identity, belief and embodiment (Dewsbury and Cloke, 2009)

Feminist and postcolonial has helped critique the construction and reproduction of place in systems of power/knowledge. In particular, contributions have stressed how place is integral to shaping academic positionalities and situated knowledges (Rose, 1997) – guiding what, how, and why we research and write exactly what we do. Unsurprisingly then, place in academia – country, region, networks, and labor production (see Sidaway, 2000) – is a contested site of social reproduction, which imbricates the academic not only into existing lines of inclusion/exclusion of knowledge but also into webs of proximate or distant relations to otherness, scripting the propensity for responsibility (Cloke, 2004).

'New' Cultural Geography 2000s–Present

The contribution of the cultural turn in informing geographic thinking on place has been widespread, even to the extent that Kirsch (2013: 1) remarks "we are all cultural geographers now," by which, he refers to the normalization of the philosophical, conceptual, and methodological underpinnings of cultural geography across human geography's subdisciplines. Although some identify this as diluting the analytical rigor of cultural geography proper (Cresswell, 2010; Wylie, 2010). If the cultural turn in the 1990s was guilty of overly textual accounts of place, representation, and meaning, recent contributions have sought to reemphasis lived practice, performance, and the materiality of place (Kirsch, 2013; *see* Materiality and Culture), alongside vitalist, post-phenomenological, and nonrepresentational approaches that emphasize the affective, embodied, and performative aspects of place (Dewsbury, 2000; Anderson and Harrison, 2010; *see* Emotion and Affect in Anthropology). These trends do not signal a renaissance of humanistic geography, but rather the inverse, decentering the human subject to focus on the materiality and liveliness of actions that constitute fleeting, but nonetheless powerful, senses of place, meaning, and experience. Meaning is not understood through preestablished systems and structures, or through the intentional consciousness of the bounded individual, instead, the focus is the *production* of meaning through ongoing habitual interaction with the world. These recent developments in sociospatial theorizing have led geographers to increasingly conceptualize place as an assemblage.

Place as Assemblage

Assemblage theory conceives places as constituted through the interplay of the material, the immaterial, and the representational (see Cresswell, 2011 on place and assemblage theory). Based on the post-structural writings of Deleuze and Guattari (1987) and De Landa (2006), geographers have begun to utilize assemblage theory to break down divisions between social–material, near–far, structure–agency to appreciate the contingency of place. That is, how places – sense of places, dwelling, locale, and even economic practices – are composed of heterogeneous elements that may be human and nonhuman, organic and inorganic, technical and natural; yet, gathered and tied together into some form of provisional sociospatial formation (Anderson and McFarlane, 2011). Anderson and McFarlane (2011) note three distinct contributions assemblage theory brings to geographical work on place. Firstly, as an analytical tool, assemblage thinking emphasizes the labor of territorialization (coherence) and deterritorialization (destabilize), the work of coalescing sociomaterial practices that may be otherwise unrelated. This accentuates the emergence rather than the resultant formation, accounting for the quality of flows that hold things together and crucially, the cracks where assemblages can be reterritorialized. The political purchase of understanding place in terms of assemblage lies in the unraveling of flows and connections that entangle heterogeneous elements to produce durable impressions of power (Connolly, 2008). Second, the notion of assemblage seeks to steer a third course between the representational and nonrepresentational, conceptualizing place as a complex and dynamic collage of things (materiality), representations, and performative practices (Cresswell, 2011). The strength of such an inquiry will be in its application, in the fine detail of connecting the embodied, fleeting ephemeral aspects of place with the discursive and expressive meanings and wider processes at work in constituting social worlds. Thirdly, assemblage is an ethos of engaging with the messiness of the world. Places are not reducible to any preexisting framework used to study them. Assemblage thinking encourages a grounded experimentation with the processes of coherence in a way that opens up seemingly dominant place-assemblages to the possibility of resistance and reconfiguration.

Placebo Effect

Abstract

The placebo effect is a context effect that is due to the psychosocial context around the therapy and the patient. Many social stimuli, which constitute the ritual of the therapeutic act, can activate a number of mechanisms in the patient's brain. Pain is the condition where most of our knowledge about placebo mechanisms comes from. Four neurotransmitters have been identified in placebo analgesia: endogenous opioids, endocannabinoids, cholecystokinin, and dopamine. Pain is not a special case, and in other conditions, such as Parkinson's disease, placebos induce similar effects.

Definition

The placebo effect, or response, is a psychobiological phenomenon occurring in the patient's brain following the administration of an inert treatment, be it an inert substance or a sham physical treatment such as sham surgery, along with verbal suggestions, or any other cue, of clinical improvement (Benedetti, 2008). It is important to point out that saline solutions or sugar pills will never acquire therapeutic properties. What matters is the psychosocial context that surrounds the inert treatment and the patient. In this sense, to the person conducting clinical trials and to the neuroscientist, the terms 'placebo effect' and 'placebo response' have different meanings. Whereas the former is interested in any improvement that may occur in the group of patients who take the inert treatment, regardless of its origin, the latter is only interested in the improvement that derives from active processes occurring in the patient's brain. In fact, the improvement in patients who are given a placebo can be ascribed to a vast array of factors, such as spontaneous remission of the disease (the so-called natural history), regression to the mean (a statistical phenomenon due to selection biases), patient's and doctor's biases, and unidentified effects of co-interventions. In pragmatic clinical trials, the researcher is interested in the improvement irrespective of its cause, because he or she only needs to establish whether the patients who take the true treatment are better off than those who take the placebo. However, if we are interested in understanding what placebo effects are and how they work, we need to separate them from spontaneous remissions, regression to the mean, biases, and the like.

Therefore, the placebo is not the inert substance alone, but rather its administration within a set of social stimuli that tell the patient that a beneficial treatment is being given (Benedetti, 2008, 2010). It is possible to rule out other phenomena by using the appropriate methodological approach. For example, to rule out spontaneous remission, the placebo group must be compared with a no-treatment group, which gives us information on the natural history of the disease. Likewise, in order to rule out biases, such as those that may occur in subjective symptoms like pain, objective outcome measures must be assessed.

Psychological Mechanisms of the Placebo Response

There is not a single placebo effect, but many, with different mechanisms across different diseases, systems, and therapeutic interventions. Sometimes it is anxiety that is modulated, at some other times reward mechanisms are involved, and in some other circumstances different types of learning, or even genetic variants, may take place in placebo responsiveness.

Most of the research on placebos has focused on expectations as the main factor involved in placebo responsiveness. In the many studies in the literature where expectations are analyzed, the terms 'effects of placebos' and 'effects of expectations' are frequently used interchangeably. In general, expectation is aimed at preparing the body to anticipate an event in order to better cope with it. There are several mechanisms through which expectation of a future event may affect different physiological functions. For example, the expectation of a negative outcome is aimed at anticipating a possible threat, thus increasing anxiety, whereas the expectation of a forthcoming positive outcome may reduce anxiety and/or activate the neuronal networks of reward mechanisms. Anxiety has been found to be reduced after placebo administration in some studies. If one expects a distressing symptom to subside shortly, anxiety tends to decrease (Price et al., 2008; Finniss et al., 2010).

The best evidence that anxiety takes part in placebo responses is shown by the nocebo effect, which is opposite to the placebo effect. In order to induce a nocebo effect, an inert treatment is administered along with negative verbal suggestions of clinical worsening, such as pain increase. Overall, expectations of a negative outcome, such as pain increase, lead to anticipatory anxiety which in turn may result in the amplification of pain (Enck et al., 2008).

Expectations may also induce physiological changes through reward mechanisms. These mechanisms are mediated by specific neuronal circuits linking cognitive, emotional, and motor responses, and are traditionally studied in the context of the pursuit of natural (e.g., food), monetary, and drug rewards. The reward mesolimbic dopaminergic system may be activated in some circumstances when a subject expects clinical improvement after placebo administration, for example, in pain, depression, and Parkinson's disease (Benedetti, 2008; Finniss et al., 2010).

Learning is another mechanism that is central to placebo responsiveness. Subjects who suffer from a painful condition, such as headache, and who regularly consume aspirin, can associate the shape, color, and taste of the pill with pain decrease. After repeated associations, if they are given a sugar pill resembling aspirin in all respects, they will experience pain decrease. Not only can shape, color, and taste of pills be

associated with clinical improvement, but countless other stimuli as well, such as hospitals, diagnostic and therapeutic equipment, and medical personnel features. The mechanism that underlies this effect is conditioning, whereby a conditioned (neutral) stimulus, such as the color and shape of a pill, can become effective in inducing the reduction of a symptom if repeatedly associated with an unconditioned stimulus, that is, the active principle contained in the pill. This type of associative learning may represent the basis of many placebo effects, where the placebo is the conditioned (neutral) stimulus itself. Placebo effects may involve social learning as well, whereby individuals learn from one another by observation (Enck et al., 2008).

There is also some experimental evidence supporting the role of genes in some types of placebo responses, including a genetically controlled serotoninergic modulation of amygdala activity, which is linked to placebo-induced anxiety relief, and a genetically controlled monoaminergic tone, which is related to the degree of placebo responsiveness in major depressive disorder. In fact, some genetic variants have been found that are particularly responsive to placebo treatment in patients suffering from social anxiety disorder and major depressive disorder (Benedetti, 2010).

The Neuroscience of Placebos

The opioid antagonist, naloxone, is capable of blocking placebo analgesia, thus indicating that the endogenous opioid system is involved. This system is a top-down regulatory system extending from cognitive and affective cortical brain regions to the brainstem and spinal cord dorsal horns, with the ability to negatively modulate the incoming nociceptive signals (Basbaum and Fields, 1984). A number of neuroimaging studies have provided important information on the location and timing of endogenous opioid activation (Tracey, 2010). For example, *in vivo* receptor binding with positron emission tomography has shown opioid activation in the pregenual rostral anterior cingulate cortex, insula, nucleus accumbens, and dorsolateral prefrontal cortex (Wager et al., 2007). This activation is abolished by naloxone administration. Data have been provided regarding also the distal part of the antinocicepive system, namely the spinal cord, whereby activity in the dorsal horn is reduced during placebo analgesia (Eippert et al., 2009b).

There are some conditions in which the endogenous opioids are not involved in placebo analgesia, such as when the subjects had previously been exposed to non-opioid drugs. Recent experimental evidence indicates that whenever the opioid system does not take part in the placebo analgesic response, the endocannabinoid system may play a crucial role. In fact, the cannabinoid antagonist, rimonabant, has been found to block non-opioid placebo analgesic responses whereas it has no effect on opioid placebo responses (Benedetti et al., 2011a).

Another neurotransmitter identified in placebo analgesia is cholecystokinin (CCK). In fact, proglumide, a CCK antagonist, potentiates the placebo analgesic response and pentagastrin, a CCK agonist, blocks placebo analgesia, consistent with the anti-opioid action of CCK. Thus, CCK appears to play an inhibitory role in placebo analgesia that is likely to be exerted in the same areas involved in opioid transmission, although no imaging data are at present available. Interestingly, CCK also modulates the counterpart of placebo analgesia – nocebo hyperalgesia – in which an increase in pain occurs following expectations of a negative outcome. In this case, by antagonizing the pronociceptive effect of CCK, proglumide produces the inhibition of the nocebo response (Enck et al., 2008).

Dopamine has been found to be involved in the placebo effect as well. It was first implicated in placebo research in investigations on Parkinson's disease (de la Fuente-Fernandez et al., 2001). It was noted that the motor placebo response in Parkinsonian patients was associated not only with dopamine release in the dorsal striatum, consistent with the role of this structure in motor control, but also in the ventral striatum (nucleus accumbens), which is part of the reward circuit. A placebo-related activation of dopamine in the reward network has also been demonstrated in pain.

While for placebo analgesia a complex and varied neurochemical picture has been gradually outlined, the running portrayal of placebo effects in Parkinson's disease is still quite straightforward, involving only dopamine. In the simulation of a classic clinical trial, patients in the placebo arm, aware of a 50% chance of receiving the dopamine agonist apomorphine, exhibited an extracellular dopamine increase of more than 200%, comparable to the response to amphetamine in healthy subjects (de la Fuente-Fernandez et al., 2001). Placebo administration has also been found to decrease the firing rate of the subthalamic nucleus neurons and change their pattern of activity from bursting to nonbursting. In addition, placebos decrease the firing rate in the substantia nigra pars reticulata and increase neuronal activity in the ventral anterior and ventral anterior lateral thalamus, suggesting that these neuronal changes are due to dopamine release (Benedetti, 2008, 2010).

Little is known about the underlying mechanisms of the placebo response in depression. The main problem is represented by the fact that, unlike single-dose trials of an intervention, such as oral or intravenous analgesia or anti-Parkinson acute therapy studies, antidepressants do not work acutely, requiring on average a minimum of two to three weeks to see clinical effects. Therefore, investigating placebo effects in depression is difficult from both ethical and methodological viewpoints. For example, if one wants to compare a placebo group with a no-treatment group to rule out spontaneous remission, this requires that some patients need not to be treated for a long period of time. This is one of the main reasons why depression, albeit an interesting model for placebo studies, has not been investigated in detail so far. Changes in brain glucose metabolism were measured by means of positron emission tomography in patients with unipolar depression who were treated with either placebo or fluoxetine for 6 weeks, and common and unique responses were described. Both placebo and fluoxetine induced regional metabolic increases in the prefrontal, anterior cingulate, premotor, parietal, posterior insula, and posterior cingulate, and metabolic decreases in the subgenual, para-hippocampus, and thalamus, with larger responses to fluoxetine compared to placebo. However, fluoxetine responses were associated with additional subcortical and limbic changes in the brainstem, striatum, anterior insula, and hippocampus. By contrast, there were no regional changes unique to placebo at 6 weeks.

Interestingly, there were unique ventral striatal (nucleus accumbens) and orbital frontal changes in both placebo and drug responders at 1 week of treatment, that is, well before clinical benefit, which suggests that they were related to expectation and anticipation of the clinical benefit. Such changes were seen neither in the eventual drug nonresponders nor at 6 weeks when the antidepressant response was well established, consistent with an expectation pattern of response (Mayberg et al., 2002). It should be pointed out that the same involvement of the ventral striatum (nucleus accumbens) was found after placebo administration in Parkinson's disease and in pain, which emphasizes once again the important role of reward mechanisms in some placebo responses.

Unconscious conditioning seems to be the sole mechanism involved in the generation of the placebo response in the case of those physiological functions that are only subconsciously controlled, like those involving the immune or the endocrine systems. Thus, placebo modulation of growth hormone (GH) and cortisol secretion could be obtained after conditioning with sumatriptan (a selective 5-$HT_{1B/1D}$ receptor agonist stimulating GH and inhibiting cortisol secretion). However, it was impossible to induce the same modulation by suggestion alone, in the absence of conditioning. It was also not possible to reverse the modulation achieved by conditioning by inducing in the subjects the opposite expectation by verbal instruction. Notably, it was indeed possible to exert this counteracting effect with the induction of opposite expectations in the case of placebo analgesia/hyperalgesia, where cognitive conscious processes play an important role (Benedetti et al., 2003).

Immune functions have also been repeatedly conditioned, both in animals and in humans. For instance, in multiple sclerosis patients, decrements in peripheral leukocyte counts induced by cyclophosphamide could be conditioned by pairing the drug with a strongly flavored beverage, and more recently, in healthy subjects, a similar conditioning with cyclosporine A produced immunosuppression after placebo, as assessed by depressed mRNA expression of IL-2 and interferon-gamma, and lymphocyte proliferation, mediated (at least in rodents) by calcineurin inhibition. Recently, much work has been devoted to the identification of the neural structures involved centrally (amygdala, insular cortex, hypothalamus) and peripherally (cholinergic and catecholaminergic output in the autonomic nervous system) in conditioned immunosuppression (Enck et al., 2008). Reflex control of immunity has been proposed to be part of a neocortical–immune axis, raising the interesting possibility of a role for cognitive factors such as expectations and beliefs in placebo immunological responses.

The Importance of the Prefrontal Lobes in Placebo Responsiveness

A functional disconnection of the prefrontal lobes from the rest of the brain is associated with a loss of placebo responsiveness. This has been investigated in patients suffering from Alzheimer's disease, in which the placebo component of an analgesic therapy is correlated with both cognitive status and functional connectivity among different brain regions (Benedetti et al., 2006). In fact, Alzheimer patients with reduced cognitive scores show reduced placebo component of an analgesic treatment and, moreover, the disruption of the placebo component occurs just when reduced connectivity of the prefrontal lobes with the rest of the brain is present. The loss of these placebo-related mechanisms reduces the overall effectiveness of the treatment, and indeed a dose increase is necessary to make up for this loss in order to produce adequate analgesia.

These data in Alzheimer's patients are supported by the correlation between white matter integrity and the magnitude of placebo responses in healthy subjects. The individual placebo analgesic effect has been found to be correlated with white matter integrity indexed by fractional anisotropy, particularly in the right dorsolateral prefrontal cortex, left rostral anterior cingulate cortex, and the periaqueductal gray. Probabilistic tractography seeded in these regions showed that stronger placebo analgesic responses were associated with increased mean fractional anisotropy values within white matter tracts connecting the periaqueductal gray with the rostral anterior cingulate cortex and the dorsolateral prefrontal cortex (Stein et al., 2012).

The important role of the prefrontal lobes in the placebo effect has been supported by the deactivation of the prefrontal cortex in the experimental setting. By combining naloxone administration with functional magnetic resonance imaging, naloxone has been found to reduce placebo effects as well as placebo-induced responses in pain-modulatory cortical structures, such as the dorsolateral prefrontal cortex and the rostral anterior cingulate cortex. In a brainstem-specific analysis, a similar naloxone modulation of placebo-induced responses in key structures of the descending pain control system, including the hypothalamus, the periaqueductal gray, and the rostral ventromedial medulla, was also found. Naloxone also abolished the increase in coupling between the rostral anterior cingulate cortex and the periaqueductal gray that was induced by the placebo (Eippert et al., 2009a). Therefore, as it occurs for prefrontal degeneration in Alzheimer's disease, placebo analgesic responses are disrupted by the pharmacological blockade of prefrontal opioidergic functioning in the experimental setting.

Prefrontal degeneration in Alzheimer's disease, reduced integrity of prefrontal white matter, and pharmacological blockade of prefrontal opioidergic transmission are not the only conditions in which placebo responses are disrupted. Repetitive transcranial magnetic stimulation has been used to inactivate the prefrontal cortex, particularly the dorsolateral prefrontal cortex, during a placebo analgesic response, and this stimulation of the prefrontal areas blocks placebo analgesia (Krummenacher et al., 2010). Therefore, the inactivation of prefrontal regions by transcranial magnetic stimulation has the same effects as those induced by prefrontal degeneration in Alzheimer's disease, reduced integrity of prefrontal white matter, and opioidergic blockade of prefrontal areas. On the basis of all of these studies, a normal functioning of prefrontal areas, as well as of the descending pain modulating network with which it is connected, appears to be critical for placebo responsiveness. In the presence of a loss of prefrontal control, we also witness a loss of placebo response.

Delivering Treatments Unknown to the Patient

In recent years, a radically different approach to the analysis of placebo effects has been implemented, in which placebo effects are assessed without placebo groups. This experimental approach consists in eliminating the placebo component and maintaining the specific effects of the treatment. In order to eliminate the placebo component, the patient is made completely unaware that a medical therapy is being carried out. Then hidden therapies are compared with open ones. The difference between the hidden and open treatment represents the placebo component, even though no placebo has been given. The importance of this approach resides in the fact that open therapies are expected whereas hidden therapies are unexpected. Therefore, the study of the open–hidden (expected–unexpected) paradigm gives us information on the role of expectations in the therapeutic outcome (Benedetti et al., 2011b).

It is possible to perform a hidden infusion of a drug by means of a computer-controlled infusion pump that is preprogrammed to deliver the drug at the desired time. The essential point is that the patient does not know that any drug is being injected. This hidden procedure is relatively easy to carry out in the postoperative phase, in which the computer-controlled infusion pump can deliver a painkiller automatically, without any doctor or nurse in the room, and with the patient being completely unaware that an analgesic treatment has been started. In general, the analgesic dose needed to reduce the pain by 50% is much higher with hidden infusions than with open ones, indicating that a hidden administration is less effective than an open one. Likewise, the time course of postsurgical pain is significantly different between open and hidden injections. In fact, during the first hour after the injection, pain ratings are much higher with a hidden injection than with an open one. Pain is not a special case, and the same results have been obtained for anxiety and Parkinson's disease (Benedetti et al., 2011b).

From the Clinical Setting to Physical Performance

As for the clinic, also in the sport world there is a zone where placebos (and nocebos) can exert their influence. Here too, chemicals such as vitamins, ergogenic aids, or diet supplements are handed out, or physical treatments and manipulations of different kinds are delivered, and expectations about their effects are set in motion in the athlete's brain. In spite of very different experimental conditions, ranging from short anaerobic sprints to long aerobic endurance cycling, and across many different outcome measures, such as mean power output, time, speed, weight lifted, or perceived exertion, all of the data indicate that athletes' expectations are important factors in physical performance, to be taken into account in training strategies (Pollo et al., 2011).

Contrary to other areas of placebo research, in physical performance knowledge about underlying mechanisms is still scant. Apart from a role for endogenous opioids in placebo pain endurance, not much is known at present. In many studies, athletes are asked to perform at their limit, in an all-out effort. Placebos apparently act by pushing this limit forward, possibly impacting on a central governor of fatigue which, although not identified, has been proposed as a brain center integrating peripheral signals (such as heart and respiratory rate, lactate, carbohydrate availability, and mechanical strain) and central control processes, so as to continuously regulate exercise performance that avoids reaching maximal physiological capacity. This would provide protection against damage on one side and constant availability of a reserve capacity on the other. By altering expectations, placebos could then represent a psychological means to signal the central governor to release the brake, allowing an increase in performance.

This article is a revision of the previous edition article by E. Shapiro, volume 17, pp. 11455–11460, © 2001, Elsevier Ltd.

Abstract

Placebo-controlled, double-blind studies are the most common research method to evaluate new, pharmacological interventions in medicine. It is important to separate this usage of the concept from the employment of substances and interventions in medicine whose causal-mechanistic effects are unknown, and yet are applied to patients' benefit. This therapeutic usage of placebo-effects has recently been termed 'the meaning response' or 'the self-healing response.' While clinical, placebo-controlled studies are designed to minimize such effects, therapeutic systems of all kinds intend to maximize them. This article reviews some historical and empirical data pertinent to these discussions, and some problems are highlighted.

Placebo-controlled, double-blind studies are the most common research method to evaluate new pharmacological interventions in medicine. Demanded by regulatory agencies all around the world, they have become standard practice. The history of the placebo-controlled trial is comparatively short: inaugurated as the method of choice by the 'Cornell Conferences on Therapy' in 1946, they became universally accepted in the 1950s. Conceptually speaking, the use of placebos in research is necessary if patients and doctors are to be kept blind to the treatment provided. Thus, the placebo as an inert substance given to patients in clinical trials as a control procedure is a methodological requirement to allow for an unbiased assessment of the effect of a pharmacological intervention. It is important to separate – historically, conceptually, and practically – this usage of the concept from the employment of substances and interventions in medicine and elsewhere whose causal-mechanistic effects are either unknown, unlikely, or too weak, and yet are and have been applied to patients' benefit. This effect probably occurs because human beings are not mechanistic biological automatons, but meaning-making, complex systems with an individual history, with expectations and elaborate cognitive processes that interfere with any type of intervention to create a very complex interaction of effects. This therapeutic usage of placebo-effects has recently been termed 'the meaning response' or 'the self-healing response.' While clinical, placebo-controlled studies are designed to minimize such effects, therapeutic systems of all kinds intend to maximize them. In this article, we will review some historical and empirical data that are pertinent to these discussions, and highlight some of the problems.

Some Historical Notes

The term 'placebo' is Latin and means 'I shall please.' Its usage is derived from Psalm 116.8, which in its medieval Latin version reads "placebo Domino in regione vivorum – I shall please the Lord in the land of the living" (Shapiro and Shapiro, 1997). This psalm was part of the Christian funeral rites and was typically sung at the deathbed. In the late middle ages it became customary in England to have those rites sung by paid mourners. From this tradition, the notion of a placebo as a surrogate for the real thing, in that case the real prayer, developed and was imported into medicine, for the first time in 1785 in a medical dictionary, to signify an intervention that is used to please the patient or to substitute for the real intervention (Shapiro and Shapiro, 1997). Typically this was done either if no good treatment was known, or if the treatment was deemed too invasive, as was often the case with interventions of earlier days, such as the poisonous mercury treatments that were the only real bactericidal treatments available before the advent of antibiotics, colchicine treatment for gout, or phlebotomy as a treatment for everything of an unknown cause. Often such 'placebos' were prescribed by doctors to patients when they saw no reason to intervene but the patient wanted to be treated. So, in order to 'please' the patient, the doctor gave some cordial that the patient might deem effective but which in fact was harmless, comparable to vitamin prescriptions of our times (Kaptchuk, 1998). Some authors even call all treatments before the advent of modern day pharmacology placebo-treatments (Shapiro and Shapiro, 1997). Clearly, such a statement is predicated on the conviction that only efficacious pharmacological treatments can be 'real' treatments. We will shortly scrutinize whether this presupposition is true. Ironically, it is the research around the 'placebo' that undermines this presupposition, as it turns out that a lot of treatments that are 'placebos' from a pharmacological point of view can be very powerful because they harness the 'placebo-effect,' shorthand for the complex self-healing reaction the organism seems to be capable of in response to a complex intervention that instills meaning.

Definitions

Depending on whether a definition of a 'placebo' was attempted from the perspective of research or clinical practice, we have to deal with two completely different families of definitions. The older, widely used definition is from Shapiro and Morris (1978: p. 440):

> A placebo is defined as any therapy, or that component of any therapy, that is deliberately used for its nonspecific, psychologic, or psychophysiologic effect, or that is used for its presumed specific

> effect on a patient, symptom, or illness, but which, unknown to patent *(sic)* and therapist, is without specific activity for the condition being treated… The Placebo effect is defined as the nonspecific, psychologic or psychophysiologic effect produced by placebos.

Note that with this definition a placebo-effect is implicitly defined vis-à-vis a specific effect that is implicitly assumed to be more worthwhile. From such a vantage point any treatment that has no specific activity, or no known specific activity, or perhaps a specific activity, but not for the condition being treated, is considered a placebo. We see immediately that such a definition is problematic for various reasons. First, what is specific for treating a particular disease is very much dependent on our knowledge, our perspective, and the context. For instance, thalidomide was used for its 'specific' tranquillizing and sleep-inducing effect during pregnancy. Only later it became known that it also had very specific teratogenic effects, namely malformations of limbs – arms, fingers, legs – that were being formed during the weeks of gestation when the substance was typically used. Today, it has completely different 'specific' applications as a very specialized medication for leprosy. A second example – bloodletting, phlebotomy, was used widely in the old medicine for its purported 'specific' efficacy against a surplus of vital substances such as blood, bile, or phlegma – mucus, which were thought to be causative of diseases in the ancient medical model of Galenos, Celsus, and others. It probably helped as often as it did damage. From a modern point of view most of these indications were likely 'nonspecific.' However, modern research shows that in specific cases, for instance of high blood pressure, it can be a very specific and effective treatment, but for completely different reasons (Houschyar et al., 2012).

Thus, what counts as 'specific' is a function not only of the 'true' nature of any intervention but also of the state of knowledge or the context of usage. This can also be nicely illustrated by a singular trial that was conducted at a time when 'informed consent,' that is, the willing and knowing affirmation of a patient to be part of a trial, was not ethically required everywhere, and that was conducted to study such an effect (Bergmann et al., 1994). In this trial, 49 in-patients who suffered from pain due to cancer were randomized to either receive the information that they were part of a trial or not to be informed of this fact. Half of them received either naproxen, a pain medication that had been independently shown to have specific efficacy against pain, or placebo. Thus, a quarter of the patients received naproxen with the information that they were part of a trial, and a quarter of patients received naproxen with the assumption that it was their normal bedside medication. Another quarter of the patients received placebo within the context of a trial, expecting either naproxen or placebo, while a quarter of the patients received placebo, although they expected their active bedside medication. The interesting finding here is that naproxen given under the conditions of a trial was twice as effective as the same substance given under the condition of a bedside medication. Even more interesting is the fact that the placebo that patients received under trial conditions, that is, blind and unknowing, but expecting either naproxen or placebo, was more effective than naproxen, the specifically active substance, received under bedside conditions. This example teaches, among many others reviewed in Walach (2011) and Walach et al. (2006), that what counts as a specific effect can be highly variable.

Thus, definitions that start from the implicit, positivist assumption that there is such a thing as a 'true' 'specific' effect that science has to uncover vis-à-vis a more or less stable, nonspecific effect of placebo are hampered right from the beginning. The definition by Grünbaum (1985) tried to solve the conundrum by introducing the differentiation between 'intended' effects and 'unintended' or 'incidental' effects, the latter being the placebo-effects observed in trials. But a closer scrutiny reveals quickly that, again, this attempt at defining the placebo effect is heavily dependent on theory. What counts as 'intended' today, may be 'unintended' tomorrow, and vice versa, as the example of thalidomide above shows.

This problem occurs because of the underlying assumptions of most authors that are related to the dominant research model within behavioral science of the 1970s that is still rampant in medical research today. This assumption assumes that any intervention will have to depend on a 'true' specific effect that is 'out there' independent of context, practitioner, and historical and social situations. And this 'true specific effect' can be made visible through employing, as a methodological trick, a placebo-control that implicitly controls for all other unwanted effects such as expectation; hope; relaxation; reduction of anxiety; statistical regression to the mean; natural course of the disease, including natural healing and improvement; and all other potential psychological effects. Ironically, it was the research around placebos itself that demonstrated that this assumption is at best a very crude abstraction that can be used for registration purposes, but is not an adequate picture of reality.

For this reason, in 1995 a workshop was convened at the National Institutes of Health where specialists in placebo-research such as Dan Moerman, Howard Brody, Irving Kirsch, and others discussed the potential and scope of a new definition. This new definition developed from the realization that placebo-effects are highly individual, and more importantly, an active response of an individual agent to a complex therapeutic stimulus. Thus the placebo was defined as a 'meaning response,' that is, a response of an organism that is a complex cognitive system capable of active engagement and interaction with the environment, to a therapeutic intervention that creates meaning for that individual or fails to do so (Moerman and Jonas, 2002). For instance, if someone has a phobic response to syringes, then an intervention that requires puncturing the skin, such as injections, infusions, or even acupuncture, might create an aversive reaction because syringes are imbued with negative meaning, while for someone who entertains the concept that injections are 'more potent' than oral prescriptions, or that what is potent needs to be felt, is likely to find the same intervention more meaningful. Thus, this new definition is explicitly semiotic and individual. 'Semiotic' hereby refers to the long tradition of semiotic studies that was introduced by Charles Sanders Peirce in the United States and Ferdinand de Saussure in Europe, which aims to understand how meaning is generated by various processes of signification, not only within language systems but also within extralinguistic modes, such as actions or cultural practices. This definition is clearly most

relevant for all therapeutic applications because it recognizes the individual nature of the response of a person to any type of intervention.

The History of Placebo-Controls

Blinding of researchers, patients, and providers is necessary if we want to know about the isolated effect of a particular intervention. This reasoning can be traced back to the middle ages, where Roger Bacon (1214/15–92) was one of the first to advocate 'experimentum – experience, experiment' as a systematic way of gaining knowledge about nature, also in medicine. 'Experiment' is derived from the Latin verb '*experiri* – to seek an experience, to travel,' and an '*expertus* – expert' is one who has ample experience. In those times an experiment was typically a replicable observation, mostly with optical instruments. It was the later Bacon, Francis Bacon, Chancellor to the Queen (1561–1626), who defined an experiment as a replicable manipulation, a question put to nature by a human action or intervention, whose result is nature's answer. It was this experimental thinking, understood as systematic, replicable manipulations of isolated systems that paved the way for the rise of the scientific model, first in physics and chemistry, and finally also in medicine.

Controlled experiments were rare in medicine until the middle of the nineteenth century. A pivotal experiment was the sequence of studies conducted by the French Academy of Science on the theories of Franz Anton Mesmer in Paris in 1784 (Bailly, 1784; Crabtree, 1993). Mesmer was a German doctor who claimed that a special type of magnetism exists, animal magnetism, which could be used to heal patients as well as to influence healthy people. To prove the case the Academy appointed a commission that studied a prominent student of Mesmer's, the dean of the medical school, as he 'magnetized' a 'hysteric' patient by stroking over the patient at a distance. The patient would fall into all sorts of fits, but only if she could actually see the magnetist and his movements. When the commissioners placed a curtain between the magnetist and his patients the effect was gone. This is the first known historical instance of 'blinding,' being represented here by the curtain (Kaptchuk, 1998). After this experience and the further history of hypnotism and magnetism, the power of human relationships, suggestions, and expectations in both provoking and curing symptoms became common knowledge in the medical community. Therefore, it was logical to start thinking about excluding this powerful agent if one wanted to study the 'raw' effect of interventions, bare of any human, psychological, or interactional factors. Blinding was the answer.

Thus with the rise of the pharmacological model in medicine it became ever more important to exclude these human factors of suggestion, relationship, expectation, and hope for cure. How can we blind patients and doctors when researching medical interventions? Only by dispensing medications or performing sham actions that are similar in each respect to the 'true' medication except for the important ingredients. This was the birth of the medical placebo as a control procedure in research. Note that here a therapeutic tradition of handing out comparatively harmless substances specifically for the psychological effects they might produce met the experimental research tradition that required such substances to instantiate control.

Historically, the first researchers that actually used placebos for research purposes were French homeopaths who tested homeopathic medicines, that is, medications that were produced through serial agitations and dilutions according to the teachings of the German doctor and pharmacologist Samuel Hahnemann, against identical placebos in 1832, and German homeopaths who carried out similar experiments in Nuremberg in 1834 (Stolberg, 1996). The first blinded experiment in psychology was conducted by Peirce – the introducer of semiotics – and Jastrow in 1884 in Harvard (Peirce and Jastrow, 1884). In this experiment, volunteers were blindfolded and had to distinguish the smallest difference in weight sensation they could actually perceive. Medicine started to gradually improve on these developments. There were various developments that came together:

In 1935 Sir Ronald Fisher published the first edition of his book 'The Design of Experiments' (Fisher, 1971(orig. 1935)). Here, Fisher, originally an agricultural researcher, introduced the crucial concepts of randomization, first used by John E. Coover in 1917 (Shapiro and Shapiro, 1997), and his statistical method of a frequentist approach to hypothesis testing that allowed for statistical inference and quantifying the probability of making a mistake when making an inference, given the same type of data in another experiment. Parallel developments ensued in the United States and in Germany, making it difficult to decide who has to be given precedence. In Germany, the clinical pharmacologist Paul Martini of Bonn University started to advocate double-blind testing procedures in his 1932 textbook 'Methodology of Therapeutic Trials' (Martini, 1932), which is, of course, based on earlier experiments and insights. In the United States in 1930, Torald Sollmann, head of the AMA's 'Council on Pharmacy and Chemistry,' advocated clinical experimentation in accordance with other scientific disciplines, using the terminology of 'comparative method,' 'double-blind procedure,' and referring to the 'blind test' (Shapiro and Shapiro, 1997).

In 1932 Harry Gold tested xanthine against placebo (lactose) in a single-blind trial against cardiac pain, a milestone, and in 1947 the first individually randomized and controlled clinical trial was carried out: the joint British-US streptomycin trial in tuberculosis patients published in 1948 by Sir Bradford Hill (Doll et al., 1999). It was blinded in that the assessors who judged the X-rays of the patients were unaware of which patient's X-ray they were rating. However, the control patients did not receive placebo, but bed rest only (Shapiro and Shapiro, 1997).

In the wake of these experiences a series of consensus conferences, known as the 'Cornell Conferences on Therapy' (Conferences on Therapy, 1946, 1954) decreed that research in medicine should test new substances against placebos in blinded, randomized studies as of 1946. Randomization was understood as a further essential ingredient in clinical trial methodology because it was the only way to ethically provide treatment in a blinded, placebo-controlled trial. By randomization we mean that the allocation to treatment groups is made by chance. 'Chance' or 'random choice' was performed by using a table of random numbers and allocating, for example, the next even number to treatment and the next uneven number to

control, or by throwing dice. Today, it is performed using computer algorithms, ideally in a way that does not allow the researcher or the recruiting physician to know which group the next patient will be in. This is called 'allocation concealment,' another type of blinding – in that case a blinding as to the outcome of the randomization procedure. If this allocation concealment or allocation blinding is not performed properly, then there might be a danger of bias, if, for instance, the intake-physician has a tendency to allocate more seriously ill patients to the 'real' treatment, especially if the study cannot be completely blinded as to the treatment arms. Only if randomization is performed would everyone have an equal chance. Methodologically, randomization was the only known method that could distribute all known and unknown confounders equally across groups, making unbiased statistical inference possible as advocated by Sir Ronald Fisher. Today there are other methods, such as minimization procedures that use regression algorithms to balance patients, that can in fact be more effective than randomization, but randomization still is the preferred method to avoid bias and create groups within clinical studies, especially within placebo-controlled double-blind studies.

Regulatory agencies, such as the Federal Drug Agency (FDA), the German Federal Institute of Drugs (Bundesinstitut für Arzneimittel, BfArm), and in more recent times, the European Medicines Agency, have now all adopted placebo-controlled trials as the gold standard for the approval of new pharmaceutical agents, except where a good standard already exists. Here, active comparator studies can also be conducted, comparing a new agent to an already approved standard for noninferiority, equality, or superiority. Nowadays, such placebo-controlled clinical trials are elaborate rituals that are conducted, in the majority of cases, by industrial stakeholders and pharmaceutical companies that seek approval for new drugs they have patented. Because such trials are very expensive to conduct, regulated as they are by legal frameworks such as the guideline of Good Clinical Practice, the public sector often conducts trials only some time after new substances have been licensed to market, are in broad usage, and when doubts about their efficacy or safety are being raised. A good and classical example from psychotherapy research was the study of antidepressant treatment by National Institute of Mental Health that compared a well-known and licensed pharmaceutical agent, the tricyclic imipramine, with placebo and two types of psychotherapy (Elkin et al., 1989). The most impressive result was the lack of significant differences and the comparative equality of outcomes across groups. This was mainly due to the fact that the control treatment, placebo, was quite effective.

New pharmacological agents are only required to show two independently significant results in double-blind, placebo-controlled studies for regulatory purposes to gain approval. The number of negative or undecided studies is not weighted as evidence against efficacy, although all material has to be submitted to the regulator.

This whole situation has led one astute observer and insider to conclude that "Randomized trials were introduced in order to protect us from the many useless treatments on the market, but oddly enough, they have given the ultimate power of knowledge production to big pharma that now use them for getting approval for treatments of little or no value and which are often too harmful" (Gøtzsche, 2013: p. 59).

Thus the dialectics of history have led to an interesting situation: What was originally introduced as an instrument of control, enlightenment, and insight, has become an instrument of power and economic dominance. What was conceptualized as an instrument of revealing the truth has become a source of confusion. This is related to the neglected conceptual assumptions that underpin the double-blind research methods.

Tacit Presuppositions, Conundrums, and Critical Aspects

Placebo-effects in clinical trials are a mix of – at least – the following components:

- Measurement artifacts
- Statistical regression to the mean
- Natural course and fluctuations of the disease
- Concomitant treatments
- Other factors of the therapeutic setting, such as generic lifestyle advice
- Genuine psychological therapeutic effects that represent a patient's response to being treated within a trial: expectation, hope, relaxation, a reduction in anxiety, gratitude for being well cared for, conditioning effects of receiving treatment that represent a patient's learning and history with the medical system, among others.

While researchers want to discover the pharmaceutical mechanisms, patients want to know about the general chance of being healed or improved by a treatment, irrespective of the component or method. Patients do not care so much whether a treatment makes use of pharmaceutical or psychological mechanisms to improve their state, as long as it happens safely and reliably (Segar, 2012). Placebos can actually be clinically effective even when patients know that they are receiving placebo. This is elegantly demonstrated by two recent studies. They show that patients with irritable bowel syndrome and migraine patients during an attack can improve clinically and statistically significantly when given open placebo, that is, even when they know they are receiving placebo (Kam-Hansen et al., 2014; Kaptchuk et al., 2010). Such a finding calls into question the implicit assumption that only pharmacological effects whose mechanisms are known can be beneficial and should be used. In fact, purchasers have meanwhile adopted a pragmatic stance that is interested only in effectiveness. Generic clinical effectiveness can also be demonstrated by comparing a treatment against a standard treatment in an open comparative effectiveness trial. Such trials have been called for recently and are part of the new national agenda in the United States (Tinetti and Studenski, 2011).

The assumption underlying the placebo-controlled trial is the paradigm, in the sense of the historian and theoretician of science Thomas Kuhn, that the human organism can be viewed as a passive biological automaton. This was originally conceived by René Descartes in the seventeenth century in his book 'Traité de'l homme – Treatise about Man' (Descartes, 2003(orig. 1664)). Here Descartes postulated that all

animals, including the human organism, can be best understood if they are seen as biological machines, driven by forces and operating on principles that can be understood by scientific analysis and experimentation. Following this lead, the German physician Rudolf Virchow paved the way for the mechanistic turn within medicine in the 1850s. This abstraction was extremely successful in understanding physiology and pathology, coming to grips with acute and epidemic diseases, improving surgery and emergency medicine, and for all acute types of treatments.

Thomas Kuhn (1955) observed that such paradigms are operative for a large group of scientists by providing them with standard experiments, methods, and expectations. In that sense, the double-blind, placebo-controlled trial is not only a method but also a paradigm that makes the stipulation that only specific – pharmacological or psychological – effects are worthwhile and scientifically interesting. Placebo research itself is gradually calling this view into question. This research demonstrates that nonspecific psychological effects of treatments – the 'meaning response,' or the 'self-healing response' (Walach, 2013) – can be very powerful, are associated with well-known causal mechanisms in the brain and thus have a clear physiological basis, and can be therapeutically as strong as the effect of 'real' treatments (Meissner et al., 2011; Colloca et al., 2013). It points to a new research paradigm that understands human beings not as biological automatons, but as complex systems that have agency, can make decisions, respond to complex signs, generate meaning, and do not react to causes only. The complexity of the system and its cognitive processes precludes a clear prediction of a potential reaction to a pharmacological or to any stimulus, at least in the individual case and in the practical situation. And because this is so, we find many conundrums in the research literature.

The Paradox of Small Specific and Strong Generic Effects: The Example of Antidepressants

Precisely because most of the regulatory trials that have led to the licensing of antidepressant agents have been conducted by the industry, about a third of the trials have remained unpublished, most of them negative. Thus a powerful myth of specific, scientifically vindicated efficacy could build up, fostered by the publicity created through early research results. This was so because the pharmaceutical companies are the owners of their data. Although they also have to submit negative studies to the regulator, they are not obliged to publish them. But the regulator requires only two positive studies. Thus, theoretically speaking, a substance that has two studies in its favor might have as many studies not showing superiority over placebo and it would still be licensed. In fact, only 48% of all placebo-controlled studies of anxiolytic or antidepressant treatments submitted to the FDA have shown independently significant results (Khan et al., 2002). This situation allows a large marketing machinery to trumpet out overly optimistic messages about new treatments, creating huge expectations in the public and in practitioners, thus creating large therapeutic effects with only comparatively small specific effects. For instance, the 'true' effect size of antidepressant treatments, estimated including all unpublished negative studies, is $d = 0.32$, that is, only a third of a standard deviation better than placebo (Turner et al., 2008), and yet the substances are highly effective in practice with overall effect-sizes from pre- to post-treatment of 2.5 standard deviations (Rief et al., 2009), precisely because most of the treatment effect is due to a strong placebo-response (Kirsch et al., 2008).

The Efficacy Paradox

One of the tacit presuppositions of the double-blind paradigm is that the 'noise' that is being controlled for in placebo-groups is similar to statistical error variance, and hence uncorrelated and unsystematic, averaging out across treatments. This has been shown to be wrong. Treatment effects in placebo and treatment groups across various types of placebo-controlled trials of a duration of more than 12 weeks are highly correlated at $r = 0.78$ (Walach et al., 2005). The conventional wisdom, however, is that it is sufficient to look at the difference between the control treatment – placebo – and the real treatment, assuming that the variations in the control treatment can be neglected. But what if it cannot be neglected? Then we may find what has been termed the 'efficacy-paradox' (Walach, 2001). This denotes a situation where a nonspecific treatment or a treatment with a very small or negligible specific efficacy can be more effective than a treatment with a very strong specific efficacy, precisely because the nonspecific or placebo-component of the treatment is so strong (**Figure 1**). This is likely to be the case in all situations where patients and providers are very satisfied because they experience strong therapeutic effects. And yet, when probed for specific efficacy in placebo-controlled clinical

Figure 1 Schematic illustration of the efficacy paradox – Two different treatments, *x* and *y*, are tested against their respective placebo-controls. While treatment *x* is found to be nonsignificantly different from placebo and hence termed 'not efficacious,' treatment *y*, due to a larger specific effect is found efficacious. However, the effect of the placebo in treatment *x* can be larger than the total treatment effect of the specific treatment *y*. Adapted from Walach, H., 2001. The efficacy paradox in randomized controlled trials of CAM and elsewhere: beware of the placebo trap. Journal of Alternative & Complementary Medicine 7, 213–218.

trials, the purported specificity is not there, or is much smaller than expected, or much too small to explain the huge effects, as in many cases of acupuncture or other unconventional treatments. Does this mean that the treatments are worthless? Probably not. The situation rather points to the limitation of the double-blind research paradigm as an instrument of evaluation.

The Inadequacy of the Medical Model for Complex and Behavioral Interventions

The medical pharmacological model has been very powerful, probably because it was a major driver of economic growth since the decades after the Second World War. A lot of researchers have implicitly tried to conform to this model by finding out 'specific' effects of behavioral interventions, such as psychotherapies, relaxation, or meditation interventions. The implicit assumption of linear additivity of those effects seems to be quite naïve. Research shows that this additivity assumption is wrong (Kleijnen et al., 1994). Rather, nonspecific and specific effects interact in a multiplicative fashion, that is, they enhance each other in a synergistic way, or counteract each other. In a synergistic system two components together can do things that neither one single element alone nor both will be able to. An example of a synergistic system is a skilled child rider who can make a powerful horse do things that the horse would not do by itself and the child by itself could not perform either. Precisely because most therapeutic systems are implicitly designed as synergistic systems, it does not make sense to pose the typically pharmacological question of the 'specific' efficacious component of a behavioral intervention.

Some Practical Issues

To create placebos for research is not trivial, as they have to be indistinguishable from the active treatment. Thus, coloring and filling agents, size, packing, and so forth have to be matched, requiring the cooperation of manufacturers. Since most true treatments have quite distinct side-effects, patients, or doctors, or both, can sometimes tell from the lack of side-effects when they are in the placebo-group. Such unblinding seems to happen in about 30% of all trials according to our survey (Walach et al., 2005). The success of blinding is rarely checked in studies, and the extent to which it biases results is unknown. Because of this situation, active placebos are sometimes used, that is, placebos that mimic the side-effects of medications, and analyses show that this procedure increases the placebo-response and makes it more difficult to find differences between groups (Kirsch and Sapirstein, 1999).

If studies have more than two arms, comparing, for instance, two different drugs with a control condition, then it is necessary to construct two different placebos: one group will receive treatment A and placebo B, another group treatment B and a placebo for A, and a third group will receive two placebos, for A and B. Such a design is often called 'double-dummy' because two different placebos are necessary.

The ethical codes that have been developed in the wake of the Nuremberg trials in 1945, after the horrendous crimes committed by physicians on concentration camp inmates became known, require doctors to carefully consider whether placebo-controls are necessary or whether active comparator trials can be done. They also require doctors to fully inform patients about the potential harm through side-effects and benefits they might incur if they enter a trial, which they are likely to receive a placebo, and what the chances of this likelihood are. Doctors also have to consult ethical committees, usually institutional review boards, that scrutinize the protocol and the rationale for it, including the statistical planning and the power analysis. Thus, for ethical reasons, studies need to be as large as necessary to demonstrate an expected effect with a statistically sufficient probability, the so called 'statistical power,' but not larger, so as to not to submit too many patients to potentially inert placebo-treatments. It has also happened quite often that ethical committees demanded unequal randomization ratios that allow for more patients to receive true treatments. Since such ratios have to be disclosed to patients, this also alters their expectation and has made it difficult for some studies to show superiority of otherwise effective drugs, notably in the area of migraine research.

Another practical issue that arises is the fact that placebo-controlled trials are normally designed for proving efficacy, and hence are also only conducted for periods of time necessary to prove this. Very often, the drugs licensed after these trials are then used for much longer periods, with no adequate data to bolster such usage. It is therefore necessary to also look into long-term observational studies, which are typically larger and longer term and can also give information about side-effects and usefulness in the long run.

Finally, placebo-controlled trials are designed to increase internal validity. They achieve this at the expense of external validity: for instance, by introducing many exclusion criteria to homogenize the patient population, or because only a fraction of all potential patients are willing to enter a study. It is therefore necessary when gauging the usefulness of information from a placebo-controlled trial to consider inclusion criteria and the percentage of patients included and to consider the results of such trials against data from other studies, such as cohort studies in large cohorts of patients that have chosen the treatment.

Abstract

There are often good scientific and ethical reasons for using placebo controls in clinical trials. At the same time placebo use is controversial, especially when an established effective treatment is being withheld from the control group. This article gives an overview of the key ethical positions in the controversy around placebo-controlled trials. While some argue that placebo controls can only be used when withholding or delaying an established effective treatment poses no or negligible risks to participants, others hold that the risks should be low or acceptable in light of the social value of the knowledge to be gained from the research. The article also describes different positions on placebo use in trials in low- and middle-income countries where study participants may not have had access to an established effective treatment outside the trial.

Introduction

Before new medical interventions, such as drugs or biologics, are introduced to clinical practice they are normally tested in preclinical and clinical trials. In the preclinical phase, potential new interventions are tested in the laboratory and on animals. Preclinical testing is a prerequisite for clinical testing in humans, but eventually the safety and efficacy of potential new interventions must be tested in humans.

The clinical testing of investigational drugs – the focus of this article – generally proceeds in four phases. In phase I, the maximum tolerated dose of an investigational drug is tested in a small number of study participants (normally 20–50). In phase II, preliminary data on the drug's safety and efficacy are gathered in a larger group of participants (up to 100–300). Phase III trials substantiate the data on safety and efficacy in a significant number of participants (up to several thousands). Typically, the investigational drug is tested in comparison to standard treatment or a 'placebo' – an inert substance, such as a 'sugar pill' or a saline injection that is administered in the same way as the investigational drug, but contains no active substance. Placebo controls are also used in phase I and II trials, although controlled designs are less common in these early phases of clinical testing. The investigational agent is expected to have therapeutic effect in phase 3 trials. If a drug has been proven efficacious in such trials, it can be licensed for regular clinical use by regulatory authorities (e.g., the European Medicines Agency in Europe or the Food and Drug Administration (FDA) in the U.S.).

To evaluate the risk–benefit profile of an investigational drug, it is useful to compare it against placebo. In a randomized, placebo-controlled trial, the study group and the control arm are treated exactly the same, except that the study group receives an active substance. Any random events that happen during the trial (e.g., spontaneous remission), or any clinical effects that are due to positive or negative expectations regarding a treatment (e.g., placebo effect), are therefore expected to be distributed evenly between both groups. In this way, the use of a placebo control allows investigators to determine whether any differences in clinical outcomes between the study arm of a trial (receiving the investigational drug) and the placebo arm can be attributed to the drug under study. These methodological reasons for using placebo controls are also ethically relevant, given that studies without scientific and social value expose participants to risks for no good reason (Emanuel et al., 2000).

However, the use of placebo can be ethically controversial when a proven or established effective treatment exists. Some research ethicists argue that a placebo control should not be used in this situation, as this implies unjustifiably withholding an established effective treatment from participants in the control group (Freedman et al., 1996a,b; Weijer and Miller, 2004). Others consider this stance as too strict. For instance, some argue that the use of placebo controls is acceptable when withholding or delaying an established effective treatment poses low or acceptable risks to participants (WMA, 2013; Emanuel and Miller, 2001). Placebo use is more controversial still in the context of research in low- or middle-income countries (LMICs) when it is used in the presence of an established effective intervention that is not available in the community in which the trial is conducted (e.g., because it is too costly or complex to implement) (London, 2001; Ellenberg and Temple, 2000). This illustrates that the use of placebo controls in clinical trials is both ethically complex and controversial.

This article gives an overview of the ethical controversy surrounding the use of placebos as a comparator in randomized, placebo-controlled clinical trials. Importantly, the article focuses on the use of placebos as it relates to clinical trial design and does not explore other questions regarding placebo use. First, the article does not discuss the placebo effect and its potential implications for informed consent to clinical research. It is well documented that positive expectations about an intervention can improve clinical outcomes, even when patients or study participants receive an inactive treatment (placebo effect) (Kam-Hansen et al., 2014). Conversely, negative expectations may evoke a negative clinical response with patients or participants experiencing real side effects (nocebo effect) (Colloca and Finniss, 2012). These findings raise the possibility that the risk–benefit profile of a clinical trial can be influenced by manipulating participants' expectations in the informed

 http://dx.doi.org/10.1016/B978-0-08-097086-8.11011-6

consent process. While placebo and nocebo effects are relevant for evaluating the risks and potential benefits of study participation, the article does not address to what extent these effects can justify modifications of informed consent (Brim and Miller, 2013).

Second, in research on the placebo and nocebo effect itself it can be methodologically necessary to deceive study participants about the study purpose and the use of placebo interventions. For example, disclosure that participants will receive an inert substance in order to study its impact on their pain will influence their expectations and therefore influence study results. The use of deception in this and other research is discussed in a separate article in this encyclopedia.

Third, the focus of this article is on the use of placebo controls in drug trials. Trials of surgical or anesthetic interventions can involve sham ('fake') procedures that are similar to placebo controls, in that they help investigators to distinguish the effects of the intervention under study from placebo effects or random events. The risks of sham procedures can be considerable, and they can sometimes involve deliberately harming participants (e.g., surgical incision under general anesthesia). Because these features warrant separate discussion, sham procedures are not considered in this article (London and Kadane, 2002; Miller, 2003).

Finally, the present article is only concerned with the use of placebo interventions in the research context. Placebos are also used in the clinical setting as a treatment offered to patients. The ethical issues regarding the clinical use of placebos are discussed elsewhere in this encyclopedia (*see* Placebo Effect).

Rationale for Using Placebo Controls in Clinical Research

From a methodological point of view, randomized, placebo-controlled clinical trials are often considered the gold standard for testing the safety and efficacy of a potential new intervention. In such trials, participants are allocated to two (or more) arms of the trial. In the study arm, participants receive the intervention under investigation, while participants in the control arm receive a placebo. Randomization – assigning participants to the arm of a trial by chance – is the preferred method for preventing confounding and bias in controlled clinical trials. Randomization helps investigators to ensure that study groups will be similar with respect to known (e.g., age) and unknown prognostic factors (e.g., spontaneous remission). If investigators cannot predict in advance to which arm participants will be assigned, this will reduce allocation bias (Friedman et al., 2010). When combined with the use of an inert placebo in the control arm, randomization enables investigators to isolate the efficacy of an investigational drug in order to determine whether different clinical outcomes between the trial arms can be attributed to the drug under study. It is for this reason that randomized, placebo-controlled trials are often considered the gold standard in clinical trial design. Placebo-controlled trials also have a higher 'assay sensitivity' than active controlled trial designs – i.e., they have a better ability to distinguish an effective treatment from a less effective intervention (Temple and Ellenberg, 2000). In an active controlled trial, in which a new drug is compared to an existing drug, data of previous (placebo-controlled) trials are needed in order to know whether the drug in the intervention arm is indeed effective.

Importantly, these methodological considerations matter not only scientifically but also ethically, as research needs to have scientific and social value to be ethically acceptable (Emanuel et al., 2000). If the research question cannot be answered without the use of placebo controls, the use of another trial design is not scientifically valid.

Placebo controls can also help to ensure the scientific validity of a study in light of expected recruitment problems, given that placebo-controlled trials normally require smaller numbers of participants. Trial completion is a continuing challenge in clinical research generally, and it is a particular challenge in research on rare diseases where studies 'compete' for a very limited number of eligible participants. Data cannot be used when trials are not completed, hence the possibility of underrecruitment can compromise the scientific and social value of research studies. By requiring smaller numbers of participants, placebo-controlled trials reduce the possibility of underrecruitment while also exposing fewer individuals to the risks of an unproven intervention.

In addition, because placebo-controlled trials require a smaller number of participants than trials that compare existing treatments, they can be useful for consolidating the evidence to support larger and more expensive active-comparator trials. The reduced costs of placebo-controlled trials may also be a consideration when trials aim to develop low-cost interventions primarily for use in LMICs (see later). In this situation, research budgets can be so tight that alternative trial designs may not be feasible, while inclusion of an active control arm is not always necessary to decide whether or not the study intervention should be adopted by the local healthcare system (provided that some level of efficacy has been proven in the trial). For example, when an established effective treatment is not affordable locally, and likely to remain unaffordable in the future, the costs of an active-comparator trial may not be justified: if the active comparator turns out to be superior it cannot be implemented.

Moreover, placebo controls may enhance the social value of studies since randomized, placebo-controlled trials are often perceived to produce the highest level of evidence in clinical research (Barton, 2000). Although this perception of placebo-controlled trials is contested, the commonly assumed superior quality of evidence produced by placebo-controlled trials still affects the practical uptake of new interventions – or the discontinuation of routine but unproven interventions – among clinicians and policy-makers.

Finally, placebo-controlled trials are frequently preferred – or perceived to be preferred – by regulatory authorities who are responsible for approving drugs for the market. For example, the FDA in the U.S. states that "adequate and well-controlled" studies are essential to test the efficacy of drugs and mentions placebo controls as the first control option (DHHS, 2008). Many therefore believe that the FDA *requires* the use of placebo-controlled trial designs. However, the FDA

acknowledges that the use of placebo controls can be ethically problematic if there is a "known effective therapy," and "placebo or no treatment would be contrary to the interest of the patient" (DHHS, 2008). Thus, while the FDA has a methodological preference for placebo-controlled trials, it does not require such trials in order to make licensing decisions about potential new treatments (Miller, 2008).

In summary, there are often good scientific, ethical, and regulatory reasons to support placebo-controlled trials. However, the use of placebo controls is not always ethically justified and often controversial, especially when it involves withholding or delaying an established effective treatment from participants in the control arm. Before we discuss the key ethical issues surrounding placebo use in this situation, the following section briefly reviews the controversy around placebo-controlled trials from a historical perspective.

Controversy Around Placebo-Controlled Trials

Clinical research expanded enormously in the twentieth century, and randomized-controlled trials became standard practice from the 1950s and 1960s onward (Kaptchuk, 1998). The evidence-based medicine (EBM) movement in the 1980s and 1990s then declared such trials, and especially those involving a placebo control, as the methodological 'gold standard' in clinical research (Sacks et al., 1982). However, scholars in the philosophy of science and other disciplines quickly pointed out that high-quality observational studies and well-designed randomized-controlled trials may produce data of comparable quality. It is for this reason that the strict hierarchy of evidence promoted by the EBM movement, with the randomized-controlled design at the top, has been questioned (Barton, 2000; Cartwright, 2011).

These and other issues sparked a first peak of sustained ethical controversy around randomized, placebo-controlled trials in the 1980s. At the core of this debate were the fundamental ethical obligations of clinician-investigators: Should their conduct be guided by the norms of clinical care or by the norms of research? Some argued that clinician-investigators maintain therapeutic obligations toward patients who participate in clinical trials (Marquis, 1983). Given that treatment in randomized-controlled trials is determined by chance, not by what the clinician-investigator believes is best for the participant, clinician-investigators were seen to violate their therapeutic obligations when enrolling patients in such trials. Enrollment in randomized, placebo-controlled trials in the presence of established effective treatment was seen as a particularly stark violation of clinician-investigators' therapeutic obligations, as it implied withholding an effective treatment (Rothman and Michels, 1994).

To resolve the conflict between the therapeutic obligations of clinician-investigators and the need to conduct rigorous clinical research, scholars introduced the principle of clinical equipoise. In its most influential formulation, this principle holds that patients should only be enrolled in randomized-controlled trials when there is "genuine uncertainty in the medical expert community about the preferred treatment" (i.e., the community of experts is 'equally poised' between a potential new intervention and any established effective treatments; Freedman, 1987). In a state of clinical equipoise, clinicians do not have sufficient information to know which of the available treatment options (if any) is preferable, either because there is no information on what is best or because they disagree about the relative merits of this information where some prefer treatment A and others B (van der Graaf and van Delden, 2012). Therefore, clinicians as investigators do not violate their therapeutic obligations when they randomize patients to the available treatments or placebo, provided that a state of clinical equipoise with regard to these treatments and placebo obtains.

Some commentators have argued in response to these developments that the attempt to align research with the therapeutic obligations of clinicians is fundamentally flawed (Miller and Brody, 2002). On this view, research is an activity that is distinct from clinical care, and therapeutic obligations therefore do not apply in the research context. We discuss this controversy in more detail.

In addition to ethical issues on the level of the individual participant and investigator, the controversy around placebo-controlled trials also touched on issues at the population level. For instance, clinicians argued that comparative effectiveness data are often more valuable for patient care than data from randomized, placebo-controlled trials. For clinicians and patients, it is generally more interesting to know how a potential new intervention compares to an established effective treatment (if any) than whether it is better than 'nothing.' Another issue at the population level is that many expensive treatments are licensed, used, and paid for on the basis of placebo-controlled trials, when it is not clear how they compare to any existing interventions. Although consideration of these issues is essential for determining the overall acceptability of placebo-controlled trials, this article focuses largely on the ethical issues raised on the participant and investigator level.

A second peak in the ethical controversy surrounding randomized, placebo-controlled trials arose in the 1990s in the context of research in LMICs. A series of high-profile articles in *The New England Journal of Medicine* questioned the ethics of the then ongoing AZT (zidovudine) trials in LMICs (Angell, 1997; Lurie and Wolfe, 1997). Researchers were testing a short course of AZT to reduce the risk of maternal–infant HIV transmission, given that the complex and costly standard regimen in use in high-income countries (HICs) was neither feasible nor affordable in resource-poor settings. Most trials tested the short course of AZT against placebo, a trial design that – it was widely agreed – would not have been acceptable in HICs. In HICs, a placebo-controlled trial would have deprived participants in the control arm of an established effective intervention that they would have otherwise received outside the trial. Moreover, withholding this intervention was associated with significant risk, as the standard AZT regimen was proven to reduce perinatal HIV transmission from 25 to 8%. Commentators therefore argued that the AZT trials demonstrated the unjustifiable use of 'double standards' in research ethics, with study participants in LMICs being afforded lower protection than participants in HICs

(Lurie and Wolfe, 1997). This criticism was especially cutting because the trials were sponsored by HIC governments or international organizations, which arguably had the resources to provide participants in the control arm with the standard AZT regimen. However, there was deep controversy surrounding the AZT trials. Many argued that the trials were ethically justifiable because they addressed the health needs of populations in LMICs, and participants in the placebo arm were not made worse off than they would have been outside the trial (Varmus and Satcher, 1997). The ethics of AZT-type trials – which aim to develop a 'substandard' treatment specifically for use in LMICs by testing it against placebo – remains debated to this day.

Even more controversial were placebo-controlled trials in LMICs that tested potential new treatments primarily intended for use in HICs. These trials form part of a larger controversy about the 'outsourcing' of clinical research to LMICs, which is motivated by a range of factors, including the lower cost of conducting research in these countries, a generally large and ready pool of potential study participants for whom trial enrollment may be the only way of accessing medical care, and the oftentimes less onerous research regulations in LMICs (Petryna, 2009). However, outsourcing is particularly controversial when it involves the use of placebo controls that would not be considered acceptable in HICs. A prominent example for these types of trials is the 'Surfaxin trial' (Hawkins and Emanuel, 2008). In this trial, a pharmaceutical company from the U.S. proposed to test a potential new treatment to prevent respiratory distress syndrome in premature infants in Bolivia. Because four established effective treatments were on the market in the U.S. and highly effective in preventing a potentially fatal condition, a placebo-controlled trial design would not have been acceptable in the U.S. However, the company did not think it would succeed in obtaining regulatory approval for the potential new treatment based on a trial comparing their investigational agent against one of the established effective treatments. By contrast, approval based on a placebo-controlled trial was deemed feasible. The company therefore proposed to conduct the trial in Bolivia, although it did not intend to license and market the potential new treatment in Bolivia or other LMICs – the U.S. and other HICs were always the target market. Although the Surfaxin trial never took place, it became a textbook example in the ethical controversy around research in LMICs (Hawkins and Emanuel, 2008).

While AZT-type trials primarily raised questions about investigators' obligations toward individual study participants in LMICs, given that these trials aim to address local health needs, Surfaxin-type trials also raise questions about exploitation on the population level. After all, Surfaxin-type trials expose populations in LMICs to research risks even though they aim to develop interventions that will benefit populations in HICs. This article discusses issues around placebo use only insofar as they concern investigator obligations toward individual participants; readers who wish to explore questions about population-level exploitation are directed elsewhere (Hawkins and Emanuel, 2008).

The controversy around placebo-controlled trials had important ramifications for the World Medical Association's *Declaration of Helsinki*, one of the most prominent documents in research ethics. Up to the 1990s, the *Declaration* required that research participants be assured of the best proven therapeutic method, thereby effectively blocking the use of placebo controls when an established effective treatment exists. The controversy around placebo-controlled trials prompted the World Medical Association to relax its stance on placebo use – but this in turn caused much debate and initiated a rapid succession of revisions of the *Declaration* in the 2000s and 2010s (the current version dates from 2013). Many commentators believe that the *Declaration* has lost much of its authority as a result, in particular regarding the use of placebos in randomized-controlled trials (Lie; FDA, Brazil).

Key Ethical Positions

It is widely agreed that the use of placebo controls raises no ethical concerns when there is no established effective intervention for the condition under study. In this situation, a placebo-controlled trial answers the clinically relevant question whether the potential new treatment is more effective than 'nothing,' and participants are not deprived of the clinical benefits of an established effective intervention. Similarly, placebo use is uncontroversial when an investigational agent is tested as an add-on to standard care (e.g., in oncology where new chemotherapeutic agents are often used in combination with established treatments). In these trials, all participants receive standard care while also being treated with either the investigational agent or a placebo. However, the ethical positions on whether placebo use is acceptable in the presence of an established effective intervention – and, if so, under which conditions – vary widely. The key issue of contention is whether it is acceptable for investigators to expose participants to risks – understood as the likelihood of experiencing physical, psychological, or other harm as result of undergoing a study intervention or research procedure – by deliberately withholding or delaying an established effective treatment. This is also based on the assumption that the placebo interventions themselves typically pose negligible risks (e.g., ingestion of a 'sugar pill,' injection of saline solution through an existing intravenous line).

No or Negligible Risk from Withholding Treatment

Some commentators maintain that the use of placebo control is acceptable only when there is no proven or established effective intervention for the condition under study. This 'no risk' position effectively excludes the use of placebo controls in the presence of an established effective intervention. The closely related 'negligible risk' position allows the use of placebo controls in this situation, but requires that withholding or delaying an established effective intervention poses no more than negligible risks. For example, on the 'negligible risk' position, placebo use is acceptable in the case of self-limiting diseases with mild symptoms where foregoing treatment is consistent with sound medical care (e.g., allergic rhinitis).

The 'no or negligible risk' position is grounded in the idea that clinical investigators have therapeutic obligations toward research participants (Marquis, 1983) and that clinical equipoise, which is grounded in these obligations, is a necessary requirement for clinical research (see previous section; Freedman et al., 1996a,b; Weijer and Miller, 2004). According to proponents of the 'no or negligible risk' position, it is impossible for clinicians to shed their therapeutic obligations simply by taking on the role of investigator. Investigators may therefore not withhold or delay an established effective treatment from participants in the placebo arm, even if doing so only requires a 'small sacrifice' from participants and there are strong methodological reasons for using a placebo control. The 'no or negligible risk' position thus places strict limitations on clinical trial design.

Low Risks from Withholding Treatment

Many believe that the 'no or negligible risk' position is overly strict, as it disallows many valuable studies that are – in their view – ethically justifiable. These commentators frequently adopt a 'low-risk' position on the use of placebo controls when an established effective intervention exists, arguing that placebo controls may be used when (1) the risks of withholding or delaying the established effective intervention are low and (2) there are compelling methodological reasons for using a placebo control (reference). Examples for 'compelling methodological reasons' include situations where the clinical response to the established effective intervention is highly variable; the symptoms of the condition under study fluctuate and/or there is a high rate of spontaneous remission; and the condition under study is known to have a high placebo response (Miller, 2008; Millum and Grady, 2013). In these situations, it can be difficult to determine without a placebo control whether the experimental intervention is efficacious, since the condition may be improving on its own or the observed clinical response may be due to a placebo effect (Temple and Ellenberg, 2000). For example, many trials of antidepressants use placebo controls because patients with depression often have waxing and waning symptoms, and depressive symptoms are known to have a high placebo response (Stone et al., 2009).

Importantly, proponents of the 'low-risk' position have different views on what constitutes low risk. Some commentators or guidelines require that the risks of withholding or delaying an established effective intervention may only lead to temporary discomfort or fleeting harm (CIOMS, 2002). Others are more permissive and interpret low risk as constituting no risk of serious harm (WMA, 2013). Depending on which conception of low risk they endorse, proponents of the 'low-risk' position may consider the same trial as ethically acceptable or unacceptable.

Like the 'no or negligible' risk position, the 'low-risk' position is often grounded in the idea that clinician-investigators have therapeutic obligations toward research participants and that investigators must, accordingly, be in a state of clinical equipoise regarding the interventions under study (Marquis, 1983; Freedman, 1987). However, unlike those who defend a 'no or negligible risk' position, proponents of the 'low-risk' position do not regard the principle of clinical equipoise as an absolute norm that can never be overridden by other moral norms and hence excludes small sacrifices to investigators' therapeutic obligations (van der Graaf and van Delden, 2009; Beauchamp and Childress, 2013). In other words, if there is a standard of care for patients with a certain condition, but the risks of withholding this standard of care are low and placebo control may be needed for compelling reasons, violation of equipoise need not be considered as ethically problematic.

'Acceptable' Risk from Withholding Treatment

A few commentators believe that the 'low-risk' position on placebo-controlled trials still disallows many valuable and – in their view – ethically justifiable studies. These commentators agree with proponents of the 'low-risk' position that placebo use may be justified in the presence of an established effective intervention, but they reject its strict limitation on risk. According to proponents of the 'acceptable risk' position, the use of placebo controls is justified when (1) there are compelling methodological reasons for a placebo-controlled trial design and (2) the risks of withholding or delaying treatment are minimized and reasonable in relation to the knowledge to be gained from the placebo-controlled trial design (Emanuel and Miller, 2001; Miller, 2008).

Proponents of the 'acceptable risk' position typically justify their view based on role-based obligations of investigators, which are seen to be distinct from the role-based obligations of clinicians (Miller and Brody, 2002). As mentioned earlier, according to these commentators, the fundamental ethical obligation of investigators is not to promote the best clinical interests of study participants. Instead, investigators have an obligation to promote the social good by conducting scientifically and socially valuable research, while ensuring that research participants are not exposed to excessive risks for the benefit of others (principle of nonexploitation). The use of placebo controls must therefore be scrutinized like most other research procedures. This implies – consistent with the earlier-mentioned criteria for acceptable placebo use – that the risks of withholding or delaying an established effective intervention must be minimized and justified in relation to the potential clinical benefits to participants and/or the scientific and social value of the knowledge to be gained from the research (Miller and Brody, 2003, 2007; Rid and Wendler, 2011).

'Acceptable' Risk from Withholding Treatment in Research in LMICs

Questions around 'acceptable' risk from withholding or delaying an established effective treatment acquire a further dimension when trials are conducted in LMICs. Many people in LMICs do not have access to established effective interventions that are commonly used in HICs, typically because these interventions are too expensive and/or the healthcare infrastructure for their safe and effective delivery is not available (e.g., services for intravenous treatment or cooling chain for certain vaccines). This lamentable state of affairs can be attributed, at least in part, to background injustices resulting

from the corruption of local governments, international treaties that disadvantage LMIC economies, and many other factors (Pogge, 2002). A key question around the use of placebo controls in LMICs therefore is this: To what extent are the obligations of investigators influenced by background injustices?

Few will argue that background injustices have no role to play – that is, few will argue that it is acceptable for investigators to withhold or delay an established effective intervention simply because it is not available locally (London, 2001). However, commentators disagree profoundly on how background injustices shape the obligations of investigators (and research sponsors). The key issue of contention is which level of care investigators ought to provide participants in the control arm of their trials (van der Graaf and van Delden, 2009; Hawkins and Emanuel, 2008).

Some of those who believe that investigators have therapeutic obligations argue that study participants in the control arm are owed the worldwide best established intervention, independent of where they live (Angell, 1997; Nuffield, 2002; Macklin, 2004). For example, in the AZT trials described earlier, these commentators argued that the use of a placebo control was unacceptable and participants in the control arm should have received the long course of AZT, which was the best treatment available worldwide at the time. Others hold that investigators can discharge their therapeutic obligations by providing less than the worldwide best established intervention – for example, the best treatment that they can reasonably provide under the circumstances (Resnik, 1998), or the treatment that participants are entitled to outside the study according to local health care norms (London, 2001; Kukla, 2007).

Questions about the appropriate standard of care are also relevant for those who believe that investigators' primary obligation is to promote the social good while not exposing participants to excessive risks for the benefit of others (principle of nonexploitation). For these commentators, to determine whether placebo use poses excessive risk, it is necessary to compare the use of a placebo control to the relevant standard of care (i.e., it is necessary to evaluate the risks of withholding or delaying the relevant baseline treatment). Yet views on what constitutes the relevant standard of care again vary. For some, the relevant standard is the treatment that participants would have normally received, provided that the research addresses a question that is relevant to local health needs (Lie et al., 2004). For others, the relevant baseline is the treatment that participants *should* have received outside that trial as a matter of global distributive justice (Emanuel, 2012).

Finally, some commentators argue that investigators have natural obligations – obligations they possess simply because they are persons, not because they occupy a particular professional role. This line of argument becomes especially relevant in LMIC settings where background injustices and limited resources frequently lead to situations of dire need. For example, some commentators argue that investigators should sometimes provide participants in the control arm with effective treatment because all people, including investigators, have a duty to rescue those whose life or health is seriously threatened (Hawkins, 2008). On this view, this general duty of rescue requires investigators to provide an established effective treatment, if one exists, when they can prevent or treat an immediate and serious threat to a patient's life or health at reasonable cost to themselves. This position does not necessarily imply, however, that placebo use can never be justified when it involves withholding or delaying an established effective treatment for a serious condition. These commentators require that placebo be provided if the research has important social value, using a placebo control is the only way of addressing the research question, and the population that the control group represents is reasonably likely to benefit from the research. The latter condition implies that it is ethically problematic to conduct a placebo-controlled trial in an LMIC that will never benefit from the results when the investigators can conduct the trial in an LMIC where the population is highly likely to benefit (Hawkins, 2008).

Key Ethical Guidance

Most ethical guidelines for research involving human subjects adopt a version of the 'low-risk' position on placebo use in the presence of an established effective treatment, although there are exceptions. For example, Brazilian authorities adopt the 'no risk' position by endorsing the *Declaration of Helsinki* in its 2000 version, which allows placebo controls only "in studies where no proven prophylactic, diagnostic or therapeutic method exists" (Brazil, 2008). By contrast, the South African research ethics guidelines adopt an 'acceptable risk' position by allowing the use of placebo controls in the presence of an established treatment, provided that participants will not be harmed – implying, arguably, that participants will not be made worse off than they would have been outside the trial – and the risks to participants are justified by the potential benefits of the research (South Africa, 2004). **Table 1** summarizes prominent ethical guidance on the use of placebo controls in clinical trials.

Concluding Remarks

There are often good scientific, regulatory, and ethical reasons for using a placebo control in randomized-controlled clinical trials. At the same time, placebo-controlled trials are deeply controversial, in particular when the use of a placebo control involves withholding or delaying an established effective treatment from study participants. The ethical controversy goes to the very heart of research ethics, as it revolves around the question what fundamentally justifies the obligations of investigators. Most research ethics guidelines require that the risks of using placebo controls – including the risks of foregoing any established effective interventions – be minimal, and that there be compelling scientific reasons for placebo use. At the same time, the minimal risk threshold is being criticized, and the notion of compelling scientific reasons remains to be specified. Therefore, it seems safe to say that the use of placebo controls in randomized controlled trials will continue to be controversial.

Table 1 Prominent ethical guidance on placebo use in clinical research

World Medical Association Declaration of Helsinki (2013)	The benefits, risks, burdens, and effectiveness of a new intervention must be tested against those of the best proven intervention(s), except in the following circumstances: Where *no proven intervention exists*, the use of placebo, or no intervention, is acceptable; or Where for *compelling and scientifically sound methodological reasons*, the use of any intervention less effective than the best proven one, the use of placebo, or no intervention is necessary to determine the efficacy or safety of an intervention and the patients who receive any intervention less effective than the best proven one, placebo, or no intervention will *not be subject to additional risks of serious or irreversible harm* as a result of not receiving the best proven intervention. Extreme care must be taken to avoid abuse of this option.
Tri-Council Policy Statement 2 (2010)	Article 11.2 (a) A new therapy or intervention should generally be tested against an established effective therapy. (b) As with all alternative choices of a control, a placebo control is ethically acceptable in a randomized controlled clinical trial only if: its use is *scientifically and methodologically sound* in establishing the efficacy or safety of the test therapy or intervention; and *it does not compromise the safety or health of participants*; and the researcher articulates to the REB a *compelling scientific justification for the use of the placebo control*.
Brazil, Conselho Nacional de Saúde, RESOLUÇÃO CNS N° 404 (2008)	Propose the withdrawal of notes for clarification of items related to health care to be provided to volunteers and the use of placebo, since they restrict the rights of volunteers to health care, keeping the following texts of the 2000 version of the Declaration of Helsinki: (…) b) Use of placebo: The benefits, risks, burdens, and effectiveness of a new method should be tested against those of the best current prophylactic, diagnostic, and therapeutic methods. This does not exclude the use of placebo, or no treatment, in studies where *no proven prophylactic, diagnostic, or therapeutic method exists*.
Uganda, UNCST, Guidelines for Research Involving Humans (2007)	7.2 *Standard of care for research participants in control groups* (…) in general, placebo-controlled trials may be conducted provided that: 1. Based on knowledge that is available at the commencement of the trial, the new drug or device to be tested does not confer any significant benefit compared to the placebo, and a proven prophylactic, diagnostic, or therapeutic method or established effective intervention does not exist. 2. Withholding an established effective intervention would expose the research participant to at most temporary discomfort or delay in relief of symptoms; 3. Use of an established effective intervention as comparator would not yield scientifically reliable results and the use of a placebo would not add any significant risk or irreversible harm to the research participants. (…)
Council of Europe, Additional protocol concerning biomedical research (2005)	Article 23 2. In research associated with prevention, diagnosis, or treatment, participants assigned to control groups shall be assured of proven methods of prevention, diagnosis, or treatment. 3. The use of placebo is permissible where there are no methods of proven effectiveness, or where *withdrawal or withholding of such methods does not present an unacceptable risk or burden.*
CIOMS International Ethical Guidelines for Biomedical Research Involving Human Subjects (2002)	As a general rule, research subjects in the control group of a trial of a diagnostic, therapeutic, or preventive intervention should receive an established effective intervention. In some circumstances, it may be ethically acceptable to use an alternative comparator, such as placebo or 'no treatment.' Placebo may be used: ● when there is no established effective intervention; ● when withholding an established effective intervention would expose subjects to, at most, temporary discomfort or delay in relief of symptoms; ● when use of an established effective intervention as comparator would not yield scientifically reliable results and use of placebo would not add any risk of serious or irreversible harm to the subjects.

South Africa, Department of Health, Research Ethics Guidelines (2004)	2.15 The choice of intervention (placebo or some treatment) to administer to participants in the control arm of a study may require the balancing of many factors, but the welfare of participants must be paramount. (…) Ethics review committees should verify that the control is appropriate, does not impose risks that are unreasonable in relation to the anticipated benefits, and that placebo controls are not employed without compelling justification. (…) Justifications for using a placebo in the control arm are that: ● No treatment or intervention is accepted as being effective for the condition; ● Treatments or interventions are accepted as being effective for the condition, but the use of a placebo will not result in more than minimal adverse effects that are entirely reversible; ● Treatments or interventions are accepted as effective for the condition, but no scientifically justifiable control option, other than a placebo, meets the objective of the research, and the anticipated benefits of the research substantially outweigh the risks to participants. (…) Ethical guidelines that apply to controlled therapeutic trials are generally adequate to protect the rights of HIV-infected persons. A special case involves the use of placebo after an intervention has already been shown to be effective. The general principle is that the use of placebo in these circumstances is unethical. However, with increasing disparities in health care between wealthy and poor countries, therapy that has been shown to be effective is often unaffordable in resource-poor settings. This is particularly true of therapeutic advances in HIV infection, which is a far bigger health care problem in poor countries in sub-Saharan Africa than in industrialized countries. *It may on occasion be justifiable to use placebo in communities that do not have access to interventions that are the standard care in resource-rich settings*. However, placebos may only be used when the *anticipated benefits outweigh the risks* to participants, and participants will *not be harmed*, and *full justification* must be provided for use of placebo.
ICH, guideline on Choice of control group E10 (2000)	2.1.3 *Ethical issues [regarding placebo control].* When a new treatment is tested for a condition for which *no effective treatment is known*, there is usually no ethical problem with a study comparing the new treatment to placebo. Use of a placebo control may raise problems of ethics, acceptability, and feasibility, however, when an effective treatment is available for the condition under study in a proposed trial. In cases where an *available treatment is known to prevent serious harm*, such as death or irreversible morbidity in the study population, it is generally *inappropriate to use a placebo control*. There are occasional exceptions, however, such as cases in which standard therapy has toxicity so severe that many patients have refused to receive it. In other situations, when there is no serious harm, it is generally considered ethical to ask patients to participate in a placebo-controlled trial, even if they may experience discomfort as a result, provided the setting is noncoercive and patients are fully informed about available therapies and the consequences of delaying treatment. (…) Whether a particular placebo-controlled trial of a new agent will be acceptable to subjects and investigators when there is known effective therapy is a matter of investigator, patient, and institutional review board (IRB)/independent ethics committee (IEC) judgment, and acceptability may differ among ICH regions. (…).

Acknowledgments

This article has benefited from our discussions with the Council of International Organizations of Medical Sciences (CIOMS) Working Group to revise the 2001 CIOMS International Ethical Guidelines for Biomedical Research Involving Human Subjects. Ingeborg van der Tweel and Hans van Delden provided helpful comments on an earlier draft of this article. Annette Rid received funding from the People Program (Marie Curie Actions) of the European Union's Seventh Framework Program (FP7/2007-2013; REA grant no. 301816).

Plagues and Diseases in History

Abstract

In spite of the development of the medical science, during the twentieth century, individuals have observed the spread of new or reemerging diseases, from plague, cholera, and flu; measles, cancer, and malaria; to acquired immune deficiency syndrome, West Nile fever, resistant tuberculosis, virus of Ebola, Creutzfeldt-Jakob disease, and others. As individual illness is rooted in society and the environment, human life is tied up with the history of main endemic and epidemic diseases. Human health is very sensitive and adaptable to changes, so the history of disease and hygiene is the core of the new ecological history.

Disease is the sting of death and death is the necessary victory of the grave. If according to Xavier Bichat, life is resistance to death, it may be said that life is resistance to disease. Disease is involved in the mechanism of adaptation – that is, of attack, equilibrium, and defense – of the living being to its habitat. Human development and evolution, in its social, cultural, and ecological setting, might give rise to alterations in the human organism, both in body and mind, against which it must struggle. The evolution of the species, society, and culture takes place within a given environment, and this environment may alter the pathological spectrum. The human being seeks Hippocratic and Aristotelian equilibrium but, in doing so, it is frequently subjected to changes and movements that endanger this quest. As the Hippocratic texts teach, human nature is part of sacred Nature, and human life is inserted in Nature's life. Similar concepts may be found in the East in ancient Chinese and Indian cultures and in the West perhaps in the pre-Columbian cultures.

This Hippocratic thought is now renewed by ecological history, and ecological movements, highly influenced by the history of disease and the history of hygiene. As individual illness is rooted in society and the environment, human life is tied up with the history of the main endemic and epidemic diseases. It is also tied up with the history of environment: according to the new ecological history, human society develops in a cultural, biological, and physical *milieu*, acting and reacting on each other. Lands where we live are increasingly modified by human action. We are, and we will be, living the changes produced by human action (deforestation, industry, mining, new energies such as radioactivity from warfare and power stations, etc.) on the environment (biological and physical). If we hurt the Earth, Nature may hurt us. Human health is very sensitive and adaptable to changes, so the history of disease and hygiene is the core of the new ecological history.

These changes, quite frequently, depend on the human being itself, on its customs and knowledge, its social groupings, or its settlements, which lead it to avoid malaria by settling in mosquito-free zones or to control smallpox by vaccination. On other occasions, such changes do not depend on the human being but arise in the environment or within the diseases themselves, which may appear or disappear, or simply change their characteristics, of their own accord, as was the case with the 'sweating sickness' (sudor anglicus). On yet other occasions, these changes are merely due to cultural appreciations, as it has happened with certain sexual practices such as masturbation or homosexuality, which used to be framed as stigmatized diseases. On the other hand, disease is not always considered only harmful: thus it may be considered a distinction of the Gods, as was the case of epilepsy in ancient times, or among some historical aboriginal tribes. Nevertheless, the Hippocratic text *On the Sacred Disease* established the natural condition of this illness, similar to other medical affections. The same disease was associated with the devil by the Christians, and historically, it had always been a supposed distinction of great personages from Caesar to Napoleon. Disease can also be considered a way toward perfection or transformations, leading to the creation of art or to the salvation of the soul, as melancholy or sorrow were for centuries.

Disease may also have political repercussions: it is claimed that George the Third's madness gave rise to problems for the British Crown, while Roosevelt's fragile health was considered to have placed him in a weak position in the Yalta negotiations. Socially, disease has sometimes unjustly been considered the stigma of groups (as acquired immune deficiency syndrome (AIDS) for homosexuals, and poor or marginal groups, or alcoholism for black or aboriginal peoples). Medicine and politics have endeavored to preempt social changes by means of the contested eugenic theories and practices of social engineering, inspired by Francis Galton at the end of nineteenth century, which began with recommendations or laws to avoid marriages entailing risks (real or imaginary), and went on to such processes as sterilizations. Heredity is today considered an important predisposition for disease, but mostly not in a deterministic way. Hereditary conditions are thus intertwined with cultural, social, religious, and moral ones. Besides, in contrast with the stark determination of former times, there is today an attempt to draw new optimism from the possibilities of genetic modifications. Yet, in this latter respect, there is fear of a future where such a formidable force could rest in the hands of the rich and powerful.

An important renewal in the study of infectious diseases was driven by bacteriological discoveries, and the theories about infection and immunity. In this respect, Hans Zinsser in *Rats, Lice, and History* combined them with human history, proposing biographical interpretations of epidemiological

 http://dx.doi.org/10.1016/B978-0-08-097086-8.62050-0

history. The study of the transmission of pathogens through animals and human beings (as vectors and hosts), living in a physical, biological, social, and cultural environment, was crucial in bringing about a new history of disease and also much later in fueling the most recent ecological history. In the meantime, the essential contributions of historical demography and social history licensed the consideration of the history of diseases as 'biographies,' shared by human cultures, living beings, and natural environment. But with the development of accurate technologies of diagnosis, the real identification of old plagues is more and more demanding.

Ancient and Medieval Times

Paleopathology enables us to discover the high incidence of diseases in the early inhabitants of the Earth, especially where such diseases left their mark on bones. It is thus possible to detect remnants of tumors, infections, necrosis, osteoporosis, and malformations, as also traumatisms, dental alterations, rickets, rheumatism, and other diseases of the bones. Today, laboratory analysis allows the possibility of detecting remnants of other diseases, germs, or lesions, in animal or human remains, including of course the famous mummies. From the first settlements in the Fertile Crescent, changes have taken place in the relationship of man and animals with their environment and it is possible to establish an extensive catalog of diseases that have largely subsisted down to this very day. Particularly significant are the forms of settlement, the crops and hunting, and the contact of man with cattle, pets, and parasites, as well as the relations between peoples, through mixing and trade, wars, and migrations.

Malaria originated in tropical Africa, accompanying the dawn of humanity, from plasmodia infecting animals and hominids. Caused by different plasmodia (*Plasmodium vivax* and *Plasmodium falciparum* among others, with different geographical distribution), its relation with human populations is shaped by migrations and deforestation, hunting and farming, climate and soils, crops, animals and foods, and a complicated immunity resulting from ancient genetic mutations and new infections. Thus, with the early human emigrations, it expanded through Eurasia, and in the third millennia BC, malaria had already set in the early civilizations in marshy areas where the water, the climate, and the crops provided the conditions for the *Anopheles* mosquitoes to infect in crowded populations. Evidence for the existence of intermittent fevers is already to be found in ancient cultures, finding suitable conditions along the Yellow, Indus, Ganges, Euphrates, or Nile Rivers.

Different interpretations considered the disease to originate from climatic or environmental factors, from particles or small animals, because of spirits or gods, or from unbalanced or disharmonic alterations. The connection between fevers, splenomegaly, and marshy areas appears in the Hippocratic texts, such as *On Airs, Waters and Places*. Deforestation, agriculture, temperature, and a greater population density, as well as military and commercial movements, favor the spread of the disease. In Italy, in Republican times, the disease becomes acute; and it was recommended that the marshy lands be either abandoned or sold and that people should dwell on high ground – the latter being traditional advice and here defense reasons also counted. Also, the cleaning and draining of swamps was considered, this being the origin of systems of engineering sanitation. The spread of malaria got worse and worse in Rome owing to negligence and flooding, climate and agricultural changes, wars, travels, and migrations, and it reached its zenith at the time of the fall of the Roman Empire, a cataclysm to which it may have contributed. But when the old Empire declined, another frightening ghost traveled through the Mediterranean Sea.

Plagues were considered in ancient cultures as diseases originating in God's punishment, with a violent pattern, and quick and terrible diffusion, affecting and killing a large number of persons. Destructive epidemic catastrophes were narrated frequently in Mesopotamian, Biblical, Egyptian, Indian, or Chinese sources, and in 430–426 BC, Thucydides describes the plague of Athens in the war against Sparta, but it is doubtful that this case refers to the bubonic plague. This epidemic death is considered the beginning of the decline of Athenian hegemony, the crisis of the democracy, and culture of the Pericles era. Fear, war, siege of the city, and its maritime port were accompanied by the death of the great ruler Pericles. Later on, the first reliable description of this disease is that given by Rufus of Ephesus in the AD first to the second century, in the epoch of Trajan; and in the sixth century, the Plague of Justinian initiates the first great epidemic cycles of bubonic plague. Soldiers and merchants, animals and merchandises, and slaves and prisoners all contribute to linking up the extremes of the known world. A consequence of this contact was the Antonine Plague in the second century. This plague –and others – is attributed to smallpox, a disease that had already existed as far back as 3000 years ago, as certain mummies show.

In the Middle Ages, leprosy spread widely, allegedly as a result of the increasing East–West relations trough trade, travels, and wars. This biblical and present day disease is accompanied by social repulse and malignant connotations since dirtiness and overcrowding provided the conditions for the spread of the otherwise not extremely contagious *Mycobacterium leprae*. In this respect, the way to Santiago de Compostela where pilgrims slept in groups and under unhealthy and dirty conditions provided a fertile ground for this disease. Another markedly religious character is to be found in the 'Sacred Fire,' 'St Anthony's Fire,' or ergotism; a disease that developed in people eating rye infected by ergot, it was soon prevented, but reappeared during the course of severe famines.

These diseases are linked to many others that owed their spread to squalor and poverty, for example, parasites and infections, scabies, mycoses and lice, anthrax and ophthalmia. Natural catastrophes, wars, poverty, and famines were escorted by mental diseases, tuberculosis and pneumonia, traumatisms and poisonings, diarrheal diseases and fevers, as well as smallpox and measles. In the Mediterranean basin, malaria continued to be endemic with the population tending to resort to residing on the hills and mountains, far from marshy lands. The extension of malaria involved south and southeast of Asia, Central China and Japan, and also North Europe. The plague set in the growing cities with the burden of rats and fleas, making this disease an explicative example par excellence of epidemic history. A second epidemic cycle began with the Black Death in 1348. Commerce and the cities collapsed, giving rise

to the origin of the modern European kingdoms. At this time, Venice established control over persons and ships, in order to avoid the spread of plague, arriving from distant lands. Dark Ages are ending, and New Worlds are opening in culture and geography.

Modern Times

European expansion meant a sudden traffic of diseases mostly toward the New World. The discovery of America, with its scattered population devoted to agriculture, where there were no dirty cities, and where the inhabitants were devoid of immunity to the diseases of old Europe, produced an enormous demographic crisis. Certain diseases, such as smallpox (and measles) ravaged the indigenous population; this very contagious and harsh illness was introduced in the Caribbean and Mexico, and destroyed American indigenous populations. Syphilis came supposedly from America (although other human treponematoses were present in other continents), brought back by the Spaniards and it caused havoc since Renaissance in Europe and soon all around the world. Troop movements spread an unknown disease called 'tabardillo,' or 'typhus exanthematicus,' bringing about serious suffering for armies and poor people. Sea voyages led to the development of scurvy, due to the lack of fresh food.

Other diseases also voyaged overseas, such as yellow fever; although it originated from Africa, due to the commerce of slaves and merchandise, special temperature conditions and mosquitoes as vectors were required for the contagion. In the seventeenth century, it took root in Brazil and also spread to the Caribbean and throughout America, reaching New York and Boston and likewise Colombia, Ecuador, and Peru. It affected warm America and Europe, through the Iberian Peninsula. Immunity and cutoffs in commerce stalled the disease, but it remains endemic in tropical areas of America and Africa. Also, malaria arrived to America with the European conquest in sixteenth century, beginning in the Caribbean and Central America and soon spreading to South and North America, becoming endemic in hot, wet, and low lands. Malaria was combated since the seventeenth century by the use of cinchona bark (*Peruvian bark*), found in Peru, as an indigenous medical practice. Later on, the quinine – the alkaloid obtained from the bark in French laboratories – gave rise to rich industry and trade. Trees were cultivated in British and Dutch colonies, mainly in Java. After being taken in the Second World War by the Japanese army, synthetic products such as atebrine and chloroquine were obtained. Getting worse with agriculture, mining and livestock changes, settlements, and slavery trade, malaria became – together with yellow fever – a scourge along the warm and hot reaches. Throughout the American conflicts between European empires, and later during the American Independence Wars, both diseases played an important role, infecting and killing nonimmune soldiers.

Plague slowed demographic growth in Europe since the wars between modern and powerful nations, the crowded and dirty cities, and the developing trades impeded protection against the disease. The great writer Daniel Defoe remembered the terrible contagion in London in 1665 in *Journal of the Plague Year*. After the great European plague of Marseille in 1720, the relative peace of the eighteenth century allowed Western Europe to set up sea and land defenses, with Austria becoming a solid bulwark in the face of the Ottoman Empire, thus sealing off all possible spread of the plague. Toward the middle of the nineteenth century, the third wave of the disease broke out and, with the exception of Europe, it spread to all countries including Asia, Africa, and paradises like America and Australia, leaving remnants in many places. The eradication of plague in Europe was a result of the advent of public hygiene, immunity to disease, and the disappearance of rats and of the old and dirty wooden buildings. The great London Fire in 1666 'purified' the city, since the hygienic rebuilding was carried out in stone, eliminating animals and dirt.

The disappearance of plague from Europe was followed by the outbreak of cholera, which had been endemic in India for centuries. This disease was described by Western travelers in the sixteenth century and its spread to Europe and America was a consequence of pilgrimages, trade, and a lack of cleanliness in water. A great pandemic broke out in 1817 from India and spread through Eastern Africa and Southern Asia, arriving to China and the Philippines, and in a second wave, it spread through Persia reaching Russia and Poland in 1830. Then this second wave swept across Europe and reached America by 1832. Throughout 100 years, terrible waves spread from the East. However, the timely and necessary cleansing of urban water supplies helped to progressively stall its advance. Nevertheless, as late as 1892, the free Hanseatic City of Hamburg suffered an outbreak of cholera epidemic, while the neighboring Altona, governed by the Prussian Reich, was able to avoid the disease, thanks to the successful filtering of its water. Local and national governments advanced in hygiene and they attempted to bring about healthier cities by means of appropriate public health measures. The nineteenth century sees the beginning of the demographic revolution in Europe, followed by developing countries, in America for example, with a sharp decline in mortality, especially maternal–infant mortality. Old inoculation and the new vaccination proposed in 1798 by Edward Jenner fought smallpox successfully. Studies about human immunity since the last decades of nineteenth century began a new medical approach to the prevention and understanding of illness, being successful in the contention of many diseases, which have a long record of burdens and deaths. Mother care also advanced both throughout pregnancy and at childbirth and during lactation.

The rise of great and industrial cities with low-grade outskirts and the emigration of peasants to the city favored the spread of maladies associated with poverty, hard work, squalor, lack of appropriate food, and exposure of people devoid of defenses. Some of the diseases were strictly occupational as in the case of miners and textile workers who were exposed to injury, and to industrial poisons that affected the proletariat. Sir Percivall Pott described in the eighteenth century the cancer produced in professional cleaners (chimney sweep) by chemical toxics contained in soot. Many other diseases, such as cancers, will be attributed to chemical and physical aggressions, including radioactivity. Other diseases were closely related to the harsh and dirty conditions of life such as spread of typhoid fever and pulmonary diseases. Tuberculosis spread over the turn between the eighteenth and nineteenth centuries, and while it was represented as the disease in fashion, affecting

notable and distinguished people, it struck the proletariat much more severely. The same can be claimed regarding the enormous spread of syphilis, and drug abuse, beginning with alcohol and continuing with cocaine and morphine.

Contemporary Times

The discovery of the microbiological origin of infectious diseases, and of effective therapies against them, and the development of public health changed the pathological landscape in developed countries. The long way between Ignaz Semmelweis and Alexander Fleming arrived to the contention of infections in health care. The twentieth century marked the descent of the high mortality rates in countries that reached high standards of sanitary development, investing in health care and public health. Such advances have been due to public health services, hospitals, antibiotics, surgery, and vaccination, and they have been reinforced by the developments in immunology and microsurgery, pharmacology, and biotechnology and with the promising future of genetic engineering. The international health solidarity promoted by the World Health Organization (WHO), and other governmental and nongovernmental organizations (NGOs), including church missionaries, were accompanied by better governance of nations, and internationalization of information and resources. The twentieth century established a serious change in geopathology of diseases. Smallpox is the first disease to be considered totally eradicated with only some samples of the virus being kept at a few laboratories for study purposes.

A Cuban doctor (Carlos Finlay) found the method by which yellow fever is transmitted through mosquitoes (*Aedes aegypti*). After the Cuban War and during the opening of the Panama Channel, yellow fever and malaria were studied and faced by US army and American sanitarians (Walter Reed, William Gorgas), and later by the Rockefeller Foundation. Impeding mosquito reproduction and avoiding bites and spreading chemical products were useful. Fortunately, an effective vaccine against yellow fever was later discovered. During nineteenth century, malaria expanded all around the world, arriving to the central extensions of America and Eurasia. Emigrations and settlements, wars, famines, climate change, and revolutions in travels, such as railroads and steamships, contributed. During the Napoleonic Wars and the American Civil War, malaria was seriously extended, as it was also during wars and revolutions in twentieth century.

In the interwar years, the Rockefeller Foundation and the League of Nations sponsored international campaigns against the disease. Many governmental campaigns also fought against malaria; several national programs were effective, from Taiwan and China to the United States, Brazil, and Argentina, passing across the Mediterranean basin, from Italy to Egypt. Opinions and campaigns oscillated between quinine treatment, fighting against mosquitoes (by dichlorodiphenyltrichloroethane (DDT)), and improvements in life, education, and land sanitation, clearing up the marshy areas. Malaria has been eradicated from Europe thanks to drainage, improvements in crop cultivation, mechanical barriers, quinine and modern drugs such as atebrine and chloroquine, and insecticides. Colonial settlements entered tropical areas backed by quinine, nets in beds, hygiene, and sanitation, but transmissible diseases were continuously a serious burden for colonial armies, in America, Africa, or Asia. Some chemical products such as DDT were a successful support for soldiers, travelers, merchants, or settlers. Nevertheless, in 1955, the World Health Assembly, meeting in Mexico, warned against the resistance of the mosquitoes to insecticides. Mosquitoes are still today carrying both diseases, and also dengue. Chagas disease produced by *Trypanosoma cruzi* is endemic in America, and sleeping sickness caused by *Trypanosoma brucei (rhodesiense* and *gambiense)* occurs in Africa.

Today, an effort is being made to involve governments in the fight against malaria, a disease that represents a danger to nearly half of the world's population. In Africa, the situation is very serious due to the changes in agriculture and irrigation as well as in work and migrations, the political and economic problems, the severe droughts, famines and wars, the bad sanitary conditions following in the wake of housing expansion and deforestation, and harsh social and economic exploitation. Together with the WHO and the United Nations International Children's Emergency Fund (UNICEF), regional institutions such as the Pan American Health Organization and the US government are financing programs of eradication. The WHO, through the 51st World Health Assembly of 1998, set up the program 'Roll Back Malaria' and, with aid from UNICEF and the World Bank, is endeavoring to bring about economic and sanitary improvements in developing countries. In twenty-first century, The Global Fund to Fight AIDS, Tuberculosis and Malaria is attaining important amount of resources and success. Nets treated with insecticides are very useful for protection against mosquitoes. Today, hope is also placed on vaccination and in the sterilization, or genetic modification, of the mosquitoes. Yet, malaria continues to be endemic in warm zones of America, Asia, and with severe cruelty, in Africa.

The rapid increase of world population in huge metropolitan areas was accompanied by new settlements and emigrations, wars, conflicts and revolutions, and marginalization of aboriginal cultures and disinherited peoples. Throughout the past two centuries, economical, social, and political expansion of the West led to studies on tropical medicine, creating hospitals and laboratories and institutions on public health and sanitary departments. Cholera continues to be feared in Asia, between India and the Far East, and also in warm zones in America and Africa. Wars and catastrophes, travels and migrations, as well as famines and unhealthy conditions allowed the expansion of the cholera germ, the *Vibrio cholerae* isolated by Robert Koch in 1883, as was the case of the recent tragedy of Haiti. At the end of nineteenth century, the third outbreak of bubonic plague allowed its bacteriological and epidemiological description. The germ of bubonic plague *Yersinia pestis*, discovered by Yersin and Kitasato, is still to be found throughout the world. The germ is carried by rats, *Rattus rattus*: rat fleas are the arthropod vectors transmitting 'epizootic' plague to humans from rodent hosts, and related species, but transmission among humans is also possible. Almost forgotten in the developed world, with several and very effective antibiotic therapies, there is, nevertheless, always the possibility that the devil may once more send his rats to the old, rich cities.

But other viruses have taken its place in the twentieth century. Thus the very old and common influenza caused several cruel and heavy outbreaks; among many others,

influenza pandemics began in 1918 and reappeared in 1957, 1968, and 2003: these were known, respectively, as the 'Spanish flu,' which perhaps originated in the United States, the 'Asian flu,' the 'Hong Kong flu,' and the 'Avian flu,' mostly coming from Asia. Vaccines are very useful in its prevention, as they are also in the control of many infectious childhood diseases, such as measles, rubella, mumps, chicken pox, whooping cough, diphtheria, and so on. Old diseases such as poliomyelitis exploded in the United States and Europe, affecting nonimmune children, and this disease has only been controlled in developed countries by means of vaccination. During the past century, individuals have observed astonished the spread of new or reemerging diseases, from plague, cholera, influenza, measles, and malaria, to AIDS, West Nile fever, Avian flu, severe acute respiratory syndrome, resistant tuberculosis, hemorrhagic fever (Ebola virus disease), transmissible spongiform encephalopathy (Creutzfeldt-Jakob disease), and others. Unfortunately today, many frequent or rare diseases do not have adequate treatment, and many germs are developing resistance to antibiotics, a serious threat for its affectivity.

AIDS has meant a development in the study of viral infections, and this disease has associations with the exploitation of poor people, unsafe sex, and drug trading, but it also affected an elite sector, which has sprung rapid research in the field. The world commotion surrounding this disease has served both to reveal human altruism on the one hand, and, on the other, contempt toward those infected by the disease, since AIDS became more and more the lot of the poor, mostly in large areas of Africa, or India, and of downcast or marginal groups such as the chronic patients, drug addicts, prostitutes, and homosexuals. Nevertheless, heterosexual transmission through unsafe sex and transmission from mother to child are today serious dangers. Safe sex and antiretroviral treatment are the best contention, while a vaccine will be obtained perhaps in the coming future.

Mental affections were considered till modern times, as devilish, criminal, or vicious behaviors, more an ethical or social than a medical problem. In the eighteenth century, the natural explanation of mental disease was established, according to Alexander Crichton, or Philippe Pinel, and in the nineteenth and twentieth centuries, its psychogenic process, following Sigmund Freud. From Pinel to Freud, the possibility of treatment and remedy of mental disease was established, leading the soul of the patient with convictions and health measures to the cure. The discovery in recent times of some effective pharmacological drugs acting on human mind, and conduct, has allowed better treatment. Reclusion was considered a doubtful possibility, restricted to some severe problems. The old lunatic asylums, founded since Middle Ages, were being abolished or completely renewed. Nevertheless, mental illnesses wreak serious havoc at present times all around the world, affecting all ages, genders, and conditions, without any distinction. Sometimes, the misunderstanding regarding mental diseases still produces cruel treatments, harsh restrictions, or punishment.

During the past decades, economic and social improvements led to quick globalization and urbanization, with longer human life and changes in disease patterns. Political, sanitary, and economic development managed to stamp out infectious morbidity, and forms of suffering or living illnesses are changing. UNICEF and WHO, in collaboration with governments, foundations, and NGOs, promote successful campaigns of vaccination, especially focusing on children. The burden of infectious, parasitic, and transmissible diseases changed to chronic diseases and sufferings related with aging and lifestyles, likewise, nutritional disorders, cancer, or heart and brain vascular diseases. On the other hand, the increase in life expectation favors the development of Alzheimer and other chronic and degenerative diseases, neurological and muscular diseases, mental affections such as schizophrenia, mania and depression, diabetes, vascular diseases, and of course, the terrible presence of cancer. Accidents and traumatisms, due to traffic and sports, factories and radiation, or even home accidents, are something that the twenty-first century is inheriting. Blindness, deafness, dumbness, and other frequent physical and mental disabilities, with multiple origins in traumatisms or accidents, genetic, metabolic and degenerative diseases, infectious diseases such as poliomyelitis, or cerebral and vascular affections, make daily life difficult and, at the same time, make economical, institutional, and social support necessary. Incapacitating and chronic diseases lead to severe dependency and so the need for protection of disabled individuals is leading to the founding of patients' associations looking for help and justice, creating new rights and demands. Ghettos and migrations, hard work, poverty and unemployment, and some of the old drugs such as alcohol, heroine, and tobacco or new synthetic ones are causing havoc even to the rich world.

But in developing countries, the old morbidity due to transmissible diseases continues to exist, maintaining a very low life expectation. Certainly, the increase of migrations and of urban population are requiring more water, food, and energy, producing climate warming, deforestation and agriculture changes, and dangerous issues such as waste, toxics, and pollutants. Potable water, health services (medical care or medical drugs), sanitation and hygiene are urgently requested. Environmental degradation and the confrontations between national, social, and ethnic groupings are a serious danger for healthy life. China, Japan, and South Korea and other expanding countries have lived through these challenges in different ways from diverse British colonies such as Australia or India. Different traditions and cultures are extremely important to understand the relations between peoples and diseases. Death is most rampant amid the least protected and poorest people, especially women, children, and the elderly, with harsh sufferings such as wars, famine, and exploitation. Under such circumstances, diseases caused by deprivation and infection continue to be the most rampant, causing high death rates among the population. Old and new diseases, such as malaria and AIDS, are ruining great stretches of Africa. Leprosy and cholera, tuberculosis and tetanus, and many child diseases, such as mumps, measles, tetanus, or meningitis are in poor countries and populations the salt of the Earth. Private and public funds, and international solidarity, are always necessary for relieving these harsh sufferings. The United Nations Millennium Development Goals are also facing them.

According to the WHO report *Global Health Risks* (2009), the better or worse conditions for mortality and for the burden of disease are seriously conditioned by several circumstances, related to lifestyles: blood pressure, blood glucose, physical activity, alcohol and tobacco, weight, safe sex, safe water,

sanitation, and hygiene. Obviously, these circumstances and their consequences are very different, depending on the social level of individuals and the public health governance of nations and peoples. If developing countries are freeing themselves from transmissible diseases, now they are fighting against noncommunicable diseases, related to social level, health organization, and hygienic customs. Some American, Asian, and African countries are still supporting a terrible burden of disease, which is also shared by low-income population in developed countries. The Rio Political Declaration in the World Conference on Social Determinants of Health (WHO-Rio de Janeiro, Brazil, 21 October 2011) is a new call looking for equity, justice, and universality of health. It has recommended adopting better governance for health and development; promoting information, justice, and participation in policy making and during the implementation process; including civil society like indigenous people; and reducing health inequities in the health sector. This Declaration promotes research on the relationships between social determinants and differences (economic, ethnic, and gender inequalities) and health equity. We are all convinced about the relation between poverty, social discrimination, low education and low sanitation, and diseases and death.

Abstract

The article examines the two disciplinary fields of development studies and urban planning to consider what they have in common and why there has been so little connection between the two. One reason is that the focus of development studies has been on social and economic change in global South regions of the world, while planning has focused on global North regions and has been less interested in how these ideas 'travel' to the global South. The article uses public participation to illustrate how this divide between the two fields has come about.

Introduction

The article will bring together two areas of theory building, publication and practice, which, over the last several decades, have had little to do with each other: planning and development studies. It is somewhat surprising that there has been so little connection between the two fields. In broad terms, both are interested in societal change and improvement, although they have somewhat different areas of focus. The following definition of development by Beall and Fox (2009: 5) captures this sentiment:

> Thus development is fundamentally about change, and in particular progress and differentiation; development studies is an academic field of enquiry that seeks to define, critique and understand progress and differentiation; and those engaged in the practice of development seek to affect change through public action.

Beall and Fox (2009) go on to offer their own definition of progress and development, which draws on Amartya Sen's idea of freedom as both the means and end of development, and progress as the expansion of freedom to human populations across the globe. To this they add the notion of development as sustainable, implying that expanded freedom must happen in a way that does not threaten the freedom of present and future generations.

Turning to planning, a recent debate among planning scholars in various parts of the world produced a definition of urban planning for inclusion in the UN Habitat (2009: 19) Global Report on Human Settlements that makes the following points:

> Urban planning is … currently viewed as a self-conscious collective (societal) effort to imagine or re-imagine a town, city, urban region or wider territory and to translate the result into priorities for area investment, conservation measures, new and upgraded areas of settlement, strategic infrastructure investments and principles of land-use regulation …. At the core of urban planning is a concern with space … Planning also highlights a developmental movement from the past to the future … to decide between appropriate actions now in terms of their potential impact in shaping future socio-spatial relations. This future imagination is not merely a matter of short-term political expediency, but is expected to be able to project a trans-generational temporal scale, especially in relation to infrastructure investment, environmental management and quality of life.

As well as both being interested in social change and improvement, and environmental sustainability, the two fields have other aspects in common. Both are interdisciplinary in their own right: they draw on, and synthesize ideas from, a wide range of other disciplines such as geography, anthropology, economics, sociology, political science, and others in order to understand the context or problem at hand. They are also both concerned with the problem of linking knowledge and action, that is, how to translate the understanding of a context into policies, programs, and projects in order to bring about change and improvement. Both fields are also concerned with the functioning of cities. Planning, like development studies, occurs at the regional, national, and even the supranational scale, but most of the focus of planning is at the urban scale (which would include local neighborhoods within a city as well) and hence the focus in this article is on urban planning. In the case of development studies, the interest in urban development has been more ambiguous: at different periods in time cities have been sometimes seen as the engines of development and sometimes as a drain on national development resources. This will be discussed further below.

Perhaps the most significant difference, however, has been the geographical areas of focus of the two disciplines. The discipline of development studies has focused primarily on those parts of the world considered in need of development: these are the regions variously termed 'developing' or the 'global South' countries. Planning, on the other hand, emerged largely to address urban issues in 'developed' or 'global North' countries and from there the ideas were transferred and adapted to other parts of the world. It is perhaps this very different geographical focus that has resulted in the two disciplines somehow 'missing' each other, with scholars publishing in different journals and attending different conferences and hence not engaging with each other's debates and issues.

This article will discuss the formative influences in the planning and development studies fields and how both areas have engaged with urban issues. This will clarify how it has come about that the two areas with similar concerns have had little connection with each other. The section thereafter will focus on one area of research and action that has been central to both disciplines – that of participation or collaboration – in order to highlight how the two fields have approached the same issues differently.

Intellectual Influences

This section will periodize and locate the overarching formative influences on first, development studies, and then planning.

Development Studies

Beall and Fox (2009) explain how development thinking moved from a 'modernization' approach in the early 1950s to 'market-driven' approaches from the 1980s onward, along with a focus on governance and institutional issues in more recent times (Table 1).

Beall and Fox (2009: 8–19) trace thinking about development from its early roots at the time of the industrial revolution in Europe when debates centered on the nature of socioeconomic evolution and change. However, it was not until after the Second World War that the idea of development emerged as an international political agenda and a discipline in its own right. In this first era of thinking (1950s and 1960s), development was defined as 'modernization.' It was assumed that undeveloped or 'backward' economies could 'catch up' with advanced economies such as that of the United States given the right economic policies: Walter Rostow's thesis of '*Stages of Economic Growth*,' in which undeveloped countries could progress from a traditional, low-productivity economy to one of the capitalist high mass consumption, was highly influential. By the 1970s, these optimistic and confident development strategies were subject to growing critique. The 1960s economic boom had benefited many countries considered undeveloped or developing, yet in most there was little sign that these benefits had 'trickled down' to the poor. The emergence of a powerful dependency theory critique (associated with the writings of Andre Gunder Frank) suggested that poorer countries were undeveloped because of the uneven nature of the international capitalist system, which actively underdeveloped the 'peripheral' (developing) regions of the world in order to develop the 'metropole' (developed regions). A further criticism of the modernist theory of development was that the focus on macrolevel economic indicators meant that a concern with the microlevel conditions of the poor had been lost. Contributors to the development field called for a more nuanced understanding of the poor and their livelihoods, a recognition of gender differences, and approaches to development that incorporated the voices of the poor, that is, that development should be more participatory. Finally, it was at this time that a new environmental lobby began to emerge, and pointed to the negative impact of a modernist growth path on the globe's resources and environment.

While modernism and its critiques were directed primarily at the economies of the 'developing' world, the new dominant position on development of the 1980s affected all parts of the capitalist world, although in different ways. The global economic crisis of the 1970s ushered in an approach to economic policy now known as neoliberalism, in which free market liberalism together with greatly reduced state involvement in national economies was seen as an ideal. Neoliberalism remains a dominant economic paradigm even to the present day, although the economic crisis of 2008 placed assumptions of inherent market efficiency in question and has reopened debates about necessary government regulation of economies.

In countries of the global North, neoliberalism heralded the start of a period of public service privatization, monetarism, and challenges to public welfare systems. Planning, in particular, was seen as unnecessary state intervention that held back economic progress and introduced market inefficiencies. In countries of the global South, free market policies were strongly advocated as the new solution to development. Through international agencies such as the World Bank and International Monetary Fund, poorer countries were offered grants and loans to address pressing debt issues with conditionalities attached that required the introduction of neoliberal policies. These conditionalities have been termed structural adjustment policies and involved privatization of state enterprises, fiscal policy discipline and reduced public sector employment, reduced tariffs on imported goods, facilitation of foreign investment, tax reform, promoting private property rights, and deregulation of domestic markets. These policies proved disastrous for most of those countries that adopted them, and the 1980s has since been labeled the 'lost decade' of development, with rising levels of poverty and unemployment and declining health and education conditions.

Many of these policies are no longer viewed as being capable of promoting development and the nature of government and institutions was recognized as a central precondition for development. In both global North and South regions, the focus turned to the functioning of government and particularly its relationship with civil society and business. The term 'urban governance' was introduced to describe the kind of relationship between these 'stakeholders' that was needed to govern increasingly complex, globalized, and multiscalar urban and regional territories. Slater (2004: 98) has argued that the 'good governance' agenda is merely a shifting conceptual emphasis within neoliberalism, rather than a new approach to development. This agenda was shifted again in the

Table 1 Key trends in mainstream development theory, policy, and practice

1950s–1960s *Modernization/developmentalism*	*1970s* *Dependency: empowerment critique*	*1980s–1990s* *Neoliberalism*	*2000s* *Institutions and governance/security and development*
Industrial expansion through investment and interventionist economic policies; poverty reduction through economic growth and residual approaches to welfare.	Growth with redistribution; increased emphasis on poverty reduction through supporting production and basic needs; participation and empowerment.	Structural adjustment: privatization, liberalization, and deregulation of markets; reduction of subsidiaries and introduction of cost recovery.	Focus on improving accountability, transparency, rule of law, security of property rights, bureaucratic efficiency, and state effectiveness; linking of security and development agendas.

Reproduced from Beall, J., Fox, S., 2009. Cities and Development. Routledge, London, Table 1.1.

mid-1990s, he argues, with the introduction of the concept of 'social capital,' referring to the 'social glue' that creates 'institutional thickness,' i.e., networked and linked formal and informal institutions that can be operationalized to support economic activity.

Other elements of the more recent approaches to development serve to reinforce the aims of the good governance agenda. Decentralization has been promoted in order to improve governance efficiency and participation (Slater, 2004), nongovernmental organizations have increasingly been drawn into partnerships around participation and service delivery, and the concerns of earlier critics of development regarding gender, participation, and environment have now become mainstream in development approaches (Beall and Fox, 2009). Crime and violence in cities have emerged as more recent developmental concerns (World Development Report, 2011) and are seen as central obstacles to the achievement of the Millennium Development Goals. Here again, local institutions are seen as playing a major role in addressing the issue.

There is an ongoing critique of current theories of development, sometimes termed 'postdevelopment' thinking. Many of the writers in this field have drawn on anthropological perspectives and research methods to show how development programs have little benefit for the poor or directly worsen their circumstances. Li (2007), in particular, theorizes the 'inevitable' gap that occurs between development intentions and outcomes, often brought about by the requirement to frame problems in terms amenable to technical solutions. There is also a postcolonial critique from those who argue that there is an ongoing relationship of domination between metropole and a previously colonial periphery, in which intellectual domination is a key element. Scholars writing from this position argue that there are elements of a modernist development perspective, which still underlie development thinking, along with ideas that Western liberal democracy offers a universal political ideal. Authors such as Connell (2007), writing from sociology, argue that intellectual domination from the global North in this and other fields needs to be countered by building new theory from and about the global South. This is a challenge that is beginning to take hold in a number of disciplines including planning.

Cities and Development

This section considers how thinking about the role of cities in development has shifted over time, as this is important in understanding what connections there might be to the field of urban planning. Beall and Fox (2009: 19) explain that at some times, cities have been seen as drivers of modernization and at other times as obstacles to development. Early modernization theorist, Arthur Lewis, associated cities with modernity, industrialization, and economic development, and rural areas with 'backward' traditionalism and agriculture. His theory that cheap labor would flow from rural to urban areas to stimulate industrial economic growth was also present in Rostow's Stages of Economic Growth thesis. Regional planner John Friedmann linked cities to economic and political development and suggested that the encouragement of urban growth in 'backward' regional peripheries could stimulate development.

At the same time, however, rapid urbanization in 'developing' countries was giving rise to a growing informal economy and shack settlements, both regarded as the antithesis of modernization and development. Suggestions that 'over-urbanization' could represent a development problem took hold, and by the 1970s, the role of cities in development was perceived by many as negative. Rapidly growing cities were described as 'parasitic' entities that absorbed public and private resources at the expense of the rural areas and the rural poor, who were condemned to ongoing poverty. The 'urban bias thesis,' as it was termed, had a significant influence on the nature of development thought and practice, which shifted to a focus on rural development and ways to curb urbanization.

The influence of the antiurban bias thesis continues today in many regions of the global South, although this seems not to be the case in China where state-led urban development is seen to support the export orientation of the economy. Elsewhere, debates continue as to whether development stimulus should focus on urban or rural/agricultural areas. Nonetheless, there is frequently a neglect of cities and urban issues in development thinking and many international donor agencies still favor rural development projects over urban ones. In some regions, it is a position favored by local politicians whose voters are rurally based, and it allows urban governments to blame the growth of informal shack dwellers and traders on undesirable urbanization. For example, in Zimbabwe in 2005, Operation Murambatsvina (also termed Restore Order, Cleanup, and Drive out the Rubbish) targeted vendors' structures, informal businesses, and homes labeled as illegal by the government, and frequently belonging to members of the political opposition. Conservative estimates were that 700 000 people were evicted from their homes and 2.3 million people were affected in other ways. Decades of rural development (one aim of which has been to slow the movement of people out of the rural areas), has nonetheless been paralleled by rapid rates of urbanization and growing cities in many global South countries. Latin America was 78.3% urbanized in 2007 and Africa and Asia were far less urbanized at 38.7 and 40.8%, respectively, but both currently have high rates of urbanization. It is anticipated that by 2025 all the 'less developed regions' together will be 53.2% urbanized (UN Habitat, 2009), and this proportion will continue to grow. Development problems in the form of poverty, unemployment, slum settlement, lack of services, and poor health are concentrating in these growing cities, yet the focus of the development field remains on the rural areas.

Planning

Modern urban planning (Watson, 2009) emerged in the industrializing world in the latter part of the nineteenth century as a very direct response to concerns of rapid urbanization, unhealthy and polluted living conditions for the poor, vanishing open green space, and threatened political upheaval as a result. Broadly, the ambition of planning was to produce urban populations that would lead ordered and disciplined lives, in healthy environments, and develop and improve both physically and spiritually. Ways of

achieving these aims were strongly influenced by the time and place within which they were formulated. Early British town planning responded to radical and utopian socialist ideas of the time and a nostalgic longing for the village life of medieval England. One of the most influential planning forms of the time, Ebenezer Howard's Garden City, represented an attempt to recreate this village life through bringing 'green' back into towns made up of winding roads and separate cottage residences, through strict separation of land uses, and through controlling the size and growth of the town. The objectives here were twofold: social – the re-creation of a traditional way of life that was essentially anti-urban but was seen as preferable to the 'chaos' of the industrial city, and aesthetic – bringing the beauty of the countryside into the towns in the interests of both physical and spiritual health (Taylor, 1998). In France, the ideas of architect Le Corbusier in the 1920s and 1930s established the ideal of the 'modernist' city, which came to be highly influential internationally and still shapes planning in many parts of the world. Le Corbusier held that society should be highly regulated and controlled and this was to be achieved through an ideal city form that was neat, ordered, and efficient. Slums, narrow streets, and mixed-use areas should be demolished and replaced with efficient transportation corridors, residences in the form of tower blocks with open space 'flowing' between them, and land uses separated into monofunctional zones.

The primary legal tool through which these 'master' plans were implemented was the development control system or zoning scheme, which originated in Germany and spread across the United States and Europe in the early part of the twentieth century. In the United Kingdom, the important 1932 Town and Country Planning Act carried forward ideas of master planning and development control, and provided a model for much colonial planning. Land use zoning usually carried with it a particular view of urban form (in keeping with the visions of the early planners) and was enthusiastically adopted by urban middle and commercial classes who were able to use it as a way of maintaining property prices and preventing the invasion of 'less desirable' lower income residents, ethnic minorities, and traders. Early planning visions and the legal tool of land use zoning were central instruments of urban modernization from the 1950s onward, where older working class and industrial areas in global North cities were demolished to make way for urban renewal projects; freeways, which cut through urban fabric to connect center and suburbs; and new housing estates on the urban edge for the displaced poor.

These urban planning ideas came to symbolize the 'modern city': they were enthusiastically adopted in many global North cities and were exported to global South countries where they aligned comfortably with ideas of economic modernization and 'catching up with the West' as development ideals. In some parts of the global South, the planning of urban settlements was bound up not only with the 'modernizing and civilizing' mission of colonial authorities, but also with the control of urbanization processes and of the urbanizing population. On the African continent, this diffusion occurred mainly through British, German, French, and Portuguese influence, using their home-grown instruments of master planning, zoning, building regulations, and the urban models of the time – garden cities, neighborhood units, and Radburn layouts, and later, urban modernism. Many African countries still have planning legislation based on British or European planning laws from the 1930s or 1940s, revised only marginally. The most obvious problem with these forms of urban modernism is that they fail to accommodate the way of life of the majority of inhabitants in rapidly growing and largely poor and informal cities, and thus directly contribute to social and spatial marginalization.

The field of development studies shifted in the post-1960s to consider other and different approaches to development. Urban planning in cities of the global North also adopted a range of new ideas and approaches in the post-1960s, in response to neoliberalism, changing ideas on the role of government and environmental concerns. Innovation took place in the following areas: planning processes and decision making (shifts toward more participatory, democratic, and integrated processes, involving wider groupings within and beyond the state), forms of spatial planning (toward more flexible and market-friendly strategic planning at a range of scales), linking planning and environment (new concerns of environmental sustainability, climate change, and resource depletion), and some new directions in land use management. However, in many parts of the global South, planning approaches changed very little (UN Habitat, 2009). There is now a significant volume of literature that argues that urban planning in many parts of the global South fails to address the primary urban issues of the twenty-first century and that in some regions it is directly implicated in worsening poverty and the environment. The strong antiurban approach that has permeated thinking in the development studies field has influenced the planning field as well, and has (in many parts of the world) meant a relative neglect of urban planning and development issues, and even the use of planning controls by some governments to justify the discouragement of urban in-migration.

Shifts in the global economy and new development ideas (promoted particularly by international aid and development agencies) have had some impact on Southern planning, with significant regional variation. Structural adjustment policies of the 1980s, and the related cuts in the public sector, no doubt made the operation of urban planning systems slower and less efficient, and rates of urban land release that do not keep pace with demand continue to present problems in rapidly growing cities. The encouragement of decentralization that accompanied structural adjustment has not improved planning systems either, although some countries have managed better than others. Frequently, the lack of professional capacity at local government level as well as a lack of resources has meant that planning decisions *de facto* remained centralized in national government.

International development agencies have made various attempts to shift approaches to planning and administration in global South cities. Regarded as one of the largest global urban programs, the United Nations (UN) Urban Management Programme was started in 1986 by the Urban Development Unit of the World Bank in partnership with UN Centre for Human Settlements and funded by UN Development Programme. The program involved some 120 cities in 57 countries, with the overall mission of promoting socially and environmentally sustainable human settlements and adequate

shelter for all, and reducing urban poverty and social exclusion. The success rate of the program was generally mixed, for example, in Tanzania it influenced the 'forward planning' aspect of the planning system, particularly through the concept of the city development strategy, but the critical regulatory aspect of the planning system continued as before. By 2006, impatience with the conservative, exclusionary, and top–down nature of planning emerged clearly at the UN Habitat World Urban Forum in Vancouver, where the UN Habitat Executive Director accused planning of increasing social exclusion in cities through antipoor measures. She suggested that urban planning should be fundamentally reviewed to see if it was able to play a role in addressing issues in rapidly growing and poor cities and called on planning practitioners to develop a different approach that is pro-poor and inclusive, and that places the creation of livelihoods at the center of planning efforts (Watson, 2009).

Hence, while planning and development studies, as two different disciplines and professional fields of practice, have a great deal in common in terms of the overall focus of interest and objectives, they have tended to operate in relative isolation from each other. The following section expands on an example of this disconnect by examining the issue of public participation, which both disciplines have engaged with.

Participatory and Collaborative Development and Planning

In the field of development studies, public and community participation in development projects in global South regions has been a focus of theoretical and practical attention since the 1970s (Table 1). Large-scale government and agency-driven modernization projects had frequently shown little benefit (or 'trickle down') for the poor, and this revived an earlier interest in local and community management and decision making. A new participatory development movement took off in the early 1980s, strongly influenced by the work of Robert Chambers and his rapid rural appraisal approach, later termed participatory rural appraisal. The focus on rural communities in this work was in line with development thinking of the time. The method is 'bottom–up' and involves local communities in collecting and sharing information about their context and development issues. The assumption has been that participatory development projects will be better designed, have better targeted benefits, and be more cost-effective and less corrupt.

The idea of empowering poor people to take control of their own development process was taken on by agencies such as the World Bank and frequently incorporated as a condition of development funding. However, over the years, there has been extensive critique of participation within the development studies field. These critiques have focused on both the practice of participation where, it is argued, the intention has often been project efficiency and cost cutting rather than empowerment, and on the concepts of participation, where it has been argued that the issue of power relations has been misunderstood or ignored, and that concepts such as 'community' and 'social capital' have been used in a highly generalized way, ignoring the ways in which context makes a difference to the meaning of these terms. Neoliberalism has introduced a strong push toward the marketization of public services and private sector involvement and profit has often taken precedence over community empowerment.

By the early 2000s, critical development scholars were suggesting that public participation had become 'tyrannical' in its effects and was simply another form of political control (in effect an 'antipolitics machine'). The 'postdevelopment' critique, which has gained strength in the 2000s in the development studies field, has been centrally influenced by Foucauldian concepts of power and by agency-driven approaches within the field of anthropology. There appears to be little faith any more in localized, state-managed, and project-linked participatory processes to deliver empowerment. The interest has instead shifted to networks of social movements and advocacy campaigns (such as the 'right to the city' movement and the World Social Forum), in which local community-driven development practices are up-scaled into wider global actions. The work of Slum Dwellers International, which links affiliated, community-based, shack-dweller organizations in Asia, Africa, and Latin America, is an example of this. Some authors take a specifically postcolonial perspective, which challenges Western-centric forms of knowledge production, with its claims of universality, and counters this through a focus on context-specific and indigenous knowledge and recognition of social diversity and difference. Some social movements are prepared to engage directly with institutions of the state in order to secure gains (for example, the participatory budgeting process in Brazil, or Slum Dwellers International's approach of 'coproduction'); others seek greater autonomy and distance themselves from state structures. Engagements with state structures are sometimes seen as a way of transferring or reclaiming certain state functions (such as budgeting or urban services) from the state to civil society and then reconfiguring them to fit local needs.

The theory and practice of participation has therefore shifted significantly in the development studies field. The focus has been on participation linked to international agency or state-initiated development projects in global South regions, many of which have been in rural areas. A strong critique of these practices has developed over the years, although they continue in various forms. However, there is now more interest in the development studies literature in bottom–up and endogenous forms of community engagement with development processes, some of which have taken on a global reach and significance.

In the field of urban planning, the issue of participation (termed participatory, collaborative, or communicative planning) has also been a central concern, emerging in the 1980s and remaining today as a dominant issue in the planning theory literature. However, there have been very few links or connections between the two disciplines on the topic of participation over the last couple of decades: few ideas or concepts have been shared and documented practical examples have rarely crossed disciplinary boundaries. Scholars in the two fields publish in different journals and attend different conferences.

In planning, the focus of research and publication on participation has been very much on how decisions are made and agreements are reached in government-centered planning processes in countries of the global

North. Usually, this involves a situation where professional planners employed by the state are called upon to develop a long-term urban plan or a shorter term change of land uses, and are required by law to consult 'the public' and take note of their responses to planning proposals. Another possibility is that a property developer needs to secure state approval for a land investment and any public objections to this need to be taken into account through a consultative process. Much of the interest in the planning theory field has been in the nature of these processes, how democratic and fair they might be, and how they are able to actually change plans and outcomes if 'the public' wishes to do this. These situations are therefore rather different from development projects carried out in parts of the global South, although the principle of participatory decision-making processes is common to both fields.

Theorists in the urban planning field have drawn inspiration from social philosopher Jurgen Habermas to pose communication as the most important element of planning practice. They also echo Habermas' faith in civil society as a source of democracy, and as a vehicle for placing pressure on the state to act more responsively. As a result, planning theorists have argued that interaction (with stakeholders or interest groups), communicating ideas, forming arguments, debating differences in understandings, and finally reaching consensus on a course of action should form the primary activity of planners. Significantly, however, these ideas are based on a set of assumptions about the nature of society and government within which such processes can happen: stable and organized civil society where communities are prepared to rationally debate the long-term future of their environments; the possibility that consensus will be reached given sufficient debate in which dominant interests can be prevented from unreasonably exerting their power; and stable and capable governments and professionals able to manage consensus-seeking processes and interpret the results into plans and projects that can then be implemented.

In many parts of the global North, it is possible for plan decision-making processes to be managed in this way (although there is a growing literature that points to the difficulties of these processes). However, as with many other planning ideas, these ideas about communicative planning are assumed to have universal relevance and the ability to be applied in any other part of the world. But problems arise when planners in very different global South contexts attempt to apply these theories. In many parts of the global South, governments are weak, lack professional capacity, and have highly centralized decision-making processes. Planning systems and laws are often only marginally reformed from the colonial era, and their top–down and control-oriented tendencies are highly incompatible with the idea of participation and collaboration. The predominantly poor urban populations, many living in informal settlements, are usually very keen to have a say in state policies and plans that affect them, but as the ordering and controlling objectives of planning are frequently in conflict with informality, achieving consensus is far more difficult. Poorer communities themselves are usually divided in terms of their interests (e.g., tenants vs landowners), may not have a long-term commitment to particular places, and may be unwilling to peacefully accept decisions not in their favor. Where participatory planning processes are instigated, they are often an attempt at co-option rather than empowerment, echoing the conclusions of critics of participation in the development studies field.

In fact, there is a great deal that planners in the global South can learn from the field of development studies and particularly from the critiques of participatory processes in this discipline. Development studies has engaged with the issue of state-society relations in development for far longer than has been the case in the planning field, and extensive experience has been built up in global South contexts and documented. Increasingly, global South planners are being urged to adopt new approaches to urban planning (UN Habitat, 2009), which are less top–down and controlling, and more facilitative, flexible, and developmental. Hence, the practical work of planning and development is becoming more closely aligned, and it makes great sense that the two disciplines should share experiences and ideas – in the area of participation and in other respects as well.

Conclusion

This article has argued that the two disciplines of planning and development studies, while having much in common in both practical and theoretical respects, have had little to do with each other over the past decades. In part, this is because development studies have focused on problems in the global South (i.e., on those areas considered to be in need of 'development'), and planning has developed its practice and theorizing primarily in global North contexts. In planning, these ideas have then been exported to global South contexts where they may have succeeded in part in controlling and ordering urban development for urban elites, but their impact on the majority of the urban poor has been highly negative, resulting in sociospatial exclusion and marginalization in urban areas (UN Habitat, 2009; Watson, 2009).

The article has explored in more detail how the two disciplines have approached the issue of participation in development projects and urban planning. Both disciplines have been centrally concerned with this issue, yet both have developed theory and practice in different ways, using different conceptual informants and case studies. Development studies have a longer history of exploration of the field of participation but planning theory and practice has made little use of this work to inform its own theorizing. Certainly, those planning theorists interested in planning processes in global South cities would greatly benefit by drawing on the literature and debates from the development studies field. Moreover, as poverty and inequality increasingly affect cities in both the global North and South, the approaches of Southern planners to dealing with issues such as informality may well be of use to global North planners. Further, with the growing interest from planning theorists in countering the tendency to draw planning ideas only from the global North, and to also consider ideas that are informed by the contextual realities of global South cities, there is greater possibility that the two disciplines may begin to share ideas and experiences.

Planning During Post-Socialism

Abstract

This article analyzes the state of public sector planning in countries that subscribed to a Marxist, state-socialist ideology during some part of the twentieth century, and especially those countries that comprise the former Eastern Bloc (today often referred to as the 'transitional countries'). Central economic planning was a defining feature of state socialism. With its collapse, this type of planning was abandoned. During the early years of postsocialism, all types of public sector planning, including urban spatial planning, were severely weakened as well. A tentative revival of urban planning can be only recently observed.

Thirty years ago, in 1985, nearly half the world comprised countries that regarded themselves, and were regarded by others, as socialist (Alternative terms are 'state socialist' or 'communist'. Without delving into the differences between these terms, for simplicity purposes from now on I will use the term 'socialist'.). In these countries, located on five continents (predominately Europe, Asia, and Africa), a single-party-dominated political apparatus subscribed to a Marxist–Leninist philosophy. Most urban land, large real estate and means of production belonged to the state and its subsidiaries in the form of various public agencies, from municipalities to workers' collectives. The stated goal of socialist regimes was to build a prosperous, egalitarian, and classless society. A planned expansion of the economy and a planned distribution of resources among the population were the major means through which this goal was to be achieved.

Yet, today, just a handful of countries carry on the socialist banner. In itself, this fact should amply illustrate that socialism's ostensibly noble goals fell short of realization. Even among those few countries where socialism remains the formal doctrine (e.g., China), capitalist elements of market-led production and resource distribution are now embedded into the socialist system.

This essay analyzes the evolution of public sector planning (from now on, 'planning' for short) in formerly socialist countries over the last quarter of a century: from the time when the 'velvet revolutions' spread down throughout Eastern Europe until today (i.e., 1989–2014). The discussion is based primarily on the experiences of the former Eastern Bloc, which comprised the Soviet Union and its East European satellites. Today, after the breakup of the Soviet Union and the two other Eastern Bloc federations, Czechoslovakia and Yugoslavia, the region includes 28 nations situated over a sixth of the world's landmass, with a total population of about 400 million people. These nations are often referred to as 'transitional' (Hirt and Stanilov, 2009).

Planning during Socialism

Marxist–Leninists regarded capitalism as inefficient and exploitative and, therefore, fundamentally flawed socioeconomic order that contained the seeds of its self-destruction. Capitalism's alternative, state socialism (in theory, later to be followed by communism) was to ultimately triumph in the world for a number of reasons. One of them was the introduction of systematic state planning of the national economy, which would efficiently and justly guide both the production and distribution of resources, thus ostensibly avoiding capitalist-style inequality and periodic economic crises. Prior to the advent of socialism, none of the countries in the region had a record of such planning. In the Soviet Union, the first Five-Year Plan covered the years from 1928 to 1933. Similar plans were adopted in the East European countries, once these countries converted to state socialism after World War II.

The nationwide plans were the poster child of Soviet-style governance. They were prepared by armies of technocrats and stamped by the states' top legislative bodies. They comprised the tip of a strictly hierarchical system of hundreds of lower-level economic plans, which translated the national goals into priorities and strategies for all other administrative divisions (e.g., republics, provinces, cities, towns) and all economic units (e.g., factories, agricultural collectives). This extraordinary scope of the planning activities was only possible because the governing communist parties had nearly full political control over their populations, and because most urban land, large real estate, and means of production were in state ownership. The planning system was heavily centralized and highly bureaucratic. Local, municipal planning was subordinate to national economic planning. The main function of local planners was to act as technical translators of the higher-level economic goals into the physical layout of cities. For example, if state economic goals were to increase a certain type of industrial production, these goals would have typically been translated into specific mandates for the building of new factories in various cities and regions, which would in turn require that new workers be brought from the countryside. Local planners would receive instructions on expected industrial and population growth. Their job would be to plan and design the new factories, infrastructure, housing, and services. Economic and physical plannings were not fully integrated in the sense that there was little negotiation between the economic planners (who operated at the national or republican level) and the physical planners (who operated at the local or municipal level). The ones in the former group held much greater powers, although they too were subordinate to the political apparatchiks.

Land-use projections were typically conducted at the local level for larger cities and at the republican level for small towns. Local forecasts had to comply with the economic objectives and projections and the spatial standards adopted at the state level; e.g., standards for green space and dwelling space per person (on how the Soviet-era planning model worked, see for example Andrusz, 1984).

The Transition Period

The communist regimes collapsed in a domino-wave fashion throughout the region between 1989 and 1992. The immediate effect was a major political and economic crisis and, in some countries, bloody ethnic wars and national breakdown. From 1989 to 1993, the East European countries lost about a quarter of their aggregate GDP; in the Soviet successor states, aggregated GDP contracted by nearly half. Most countries of the region saw a rise in unemployment rates exceeding a quarter of the population, an explosion of inflation rates into the double and triple digits, a collapse of government-provided safety nets, and a precipitous decline of living standards for the majority of the populations. Social stratification increased sharply as measured by the increases in the Gini coefficients of income distribution throughout the region. On several accounts, the Eastern Bloc meltdown was the deepest and widest economic crisis to occur in peaceful times in modern history. Its causes are well documented and include the institutional vacuum leftover after the collapse of the one-party regimes, the obsolete state of the socialist-era industries, and the erosion of human capital (Dobrinsky et al., 2006). Political reforms and economic recovery followed at varying speeds, with some countries, especially in Central Europe and the Baltic region, leading the pack and joining the European Union (The following former Eastern Bloc countries have joined the European Union: Bulgaria, Croatia, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, Slovakia, and Slovenia.), and others still mired in poverty and unrest (Havrylyshyn, 2007). In most countries, there was a general consensus that the end-of-state socialism meant the beginning of reforms leading to market economies and democratic governance; hence, the term 'transition' – that is, a pathway from socialism to capitalism – which is commonly applied to the postsocialist period. But interpreting what market economy or what democracy means – and how to implement them – has varied significantly from country to country. In each, it has been shaped by history and traditions (e.g., see Stark, 1991 on 'path dependence'). Since strategies and end results have been so different, with some countries embracing a neoliberal version of capitalism (e.g., those in the Baltic region), others retaining elements of social-democratic welfare states (e.g., Slovenia) and third continuously exercising strong state control over resources (e.g., Russia, Kazakhstan), some authors have problematized whether the term 'transition' is accurate or applicable to all states region wide (on 'theorizing transition', see Pickles and Smith, 1998). Perhaps not all countries can be described as 'transitioning' toward capitalism; perhaps at least for some 'transformation' is a better term (on the diversity of postsocialisms, see for example, Bohle and Greskovits, 2012).

Privatization and Institutional Transformations

Regardless of the multiplicity and varying speeds of the post-socialist projects, some level of privatization of public resources was the transformative process common to all countries in the region. Privatization – the transfer of assets and functions from the public to the private sector – could well be described as the 'leitmotif' of the transition (Bodnar, 2001; Hirt, 2012). In the immediate aftermath of socialism, new constitutions guaranteed the sanctity of private property and mandated the privatization of most urban land, real estate (including almost all dwellings) and means of production, as well as many social services. Some assets were sold; others restituted to those private parties and their successors who could prove ownership predating socialist-era nationalization. In most countries, privatization and restitution were carried out during the early and mid-1990s. However, the process of restituting urban land was highly problematic. This is because often multiple private parties submitted claims to ownership and because much of the urban land was built upon during the years of socialism and thus could not be restituted back to its earlier owners without first demolishing the buildings located on it (which of course was impossible). In addition, the restitution of real estate and means of production was often characterized by corrupt dealings (e.g., large industrial enterprises were sold for pennies to former party apparatchiks). This process greatly contributed to the stratification of postsocialist societies.

Accompanied by the reintroduction of market tenets of production and consumption, privatization, and restitution fundamentally transformed economy and society, including the mechanisms of urban development and the planning process. Whereas public authorities had a near monopoly on urban development during the socialist years with the state and its subsidiaries acting as both urban planners and developers, the new paradigm of urban development involved intense competition for land and other resources between plural actors: property owners, private developers, builders, interest groups, political alliances, and nonprofit organizations, along with governments at all levels and the broader citizenry (e.g., Tsenkova and Nedovic-Budic, 2006; Stanilov, 2007). A wholly new actor in the development process were the large, multinational, typically Western (but in some countries also Chinese, Indian, Israeli, Middle Eastern, etc.) firms that entered different countries in the region at different times and in many cases secured preferential treatment from national and municipal governments, ostensibly in the name of faster economic growth. With both private and public resources severely shrinking, especially during the early years of the postsocialist transition, the competition over urban land and resources was particularly ruthless. The weakened and often passive public sector and the newly impoverished masses usually ended up on the losing side.

Another important factor transforming the urban planning and development process was institutional decentralization. National-government involvement in planning matters was sharply reduced. The practice of central economic planning was eliminated. Virtually all spatial planning powers were transferred to local, municipal institutions, whose sheer number in most countries increased dramatically. For example, in Hungary, the number of political governments doubled during

the 1990s; in Bulgaria and Slovenia it nearly tripled (Tosics, 2005). This institutional decentralization was carried out under new laws for municipal self-governance and was seen as an integral part of the overall democratization process. However, as a consequence of the economic downturn, local governments had scarce resources to engage in planning activity. Furthermore, many had no experience with proactive planning, since during socialism they had only followed national directives. As a result, local governments ended up in the peculiar position of having to plan and implement their plans but with little financial and institutional capacity to do so (Hamilton et al., 2005; Hirt and Stanilov, 2009).

Planning's Legitimacy Crisis

The ideological climate within which planning operates also changed radically throughout the region. In the aftermath of state socialism, most new governments made a sharp turn to the political right. Neoliberal doctrines espousing the superiority of free-market capitalism put into question the utility of public sector planning. Many politicians came to view planning as an unwanted vestige of the old socialist system – a phenomenon referred to as a 'legitimacy crisis' of planning (Nedovic-Budic, 2001, Hirt, 2005). This legitimacy crisis affected not just central economic planning – the type of planning that had malfunctioned during socialism and the first to be let go after its collapse. Moral devaluation affected all sorts of government policy, planning, and regulation activity. Spatial and housing policies – a traditional public-policy area in most capitalist democracies – were no longer considered an appropriate activity of higher-tier levels of government. The assumption was that the market will guide the production and distribution of resources in more efficient ways that government planners ever could. If government intervention in urban development were needed, it should be conducted by municipal governments, which are much closer to the real-life issues in their communities: hence, the transfer of planning activities to the local level, noted in the previous section. Whereas there were valid reasons to assume that local governments would be closer to the problems 'on the ground', in practice they lacked both financial and institutional resources to deal with the serious urban problems leftover from the socialist period: idle industry, decaying housing and infrastructure, environmental degradation, etc. New problems, such as growing poverty and unemployment that were induced by geopolitical and national-level events, were even further beyond what municipal governments could plan for or resolve.

Planning was seen as an outdated activity not just by politicians but by the broader citizenry as well. To a great extent, the problem arose from the legacy of the past. During the socialist period, planners were trained in the technocratic professions (architecture, civil engineering, economics, etc.). They applied their specialized knowledge to implement political priorities set by the communist leadership in the 5-year national economic plans. The highly centralized and bureaucratic system left no room for citizen participation in planning, as in other types of government decision-making. Thus, most citizens perceived planning as a faraway activity in which they had no input – a perception that greatly contributed to the profession's legitimacy crisis in the 1990s (Hirt, 2005). One of the immediate results of this crisis was that, in many towns and cities across the region, people took urban development into their own hands. To begin with, the intensity of building activities, public and private, generally decreased, as it does during any economic meltdown; new housing input dwindled especially dramatically. For example, in the early 1990s, the number of new dwelling units per year in Czechoslovakia dropped to a fifth of what it had been during the 1980s; in Bulgaria, it went down to a tenth (Stanilov, 2007: 173). But where housing and other construction did occur, an unusually high percentage of it was produced not just without long-term planning vision behind it but without government involvement of any sort, even without a building permit. Especially in the nations where ethnic conflict raged on for years, such as the former Yugoslavia and some of the post-Soviet republics, urban informality became the new norm (Tsenkova, 2012). The problem was aggravated by the fact that updated urban planning laws and regulations did not even exist. Through the 1990s, the last valid master plans of many cities dated back to the socialist 1960s and 70s. They were irrelevant and thus largely ignored. Urban development occurred on a piecemeal basis, with private parties often building whatever they wish where they wish – a process sometimes dubbed as 'investor urbanism' or even 'anarchitecture' (Hirt, 2012).

Whereas public sector withdrawal from urban involvement and ad hoc development became widespread, there are exceptions. In the capital cities of newly independent countries, such as those in the Baltic region and the former Yugoslavia, significant public-sponsored building activities were initiated with the goal of changing the architectural heritage to reflect new national identities (Czaplicka et al., 2009). Similar outcomes can be seen in some of large and economically powerful Soviet successor states, where national governments have invested enormous resources in endowing their capitals with a 'global-city' look (e.g., Astana, Kazakhstan) or where powerful city administrations have partnered with large private development corporations to the same end (e.g., Moscow and Saint Petersburg, Russia).

Pressing Challenges and New Planning Instruments

Many of the severe new challenges of the transition period, such as declining living standards and sharp social stratification, were a result of the broad economic decline and institutional instability of the transition period. However, other challenges arose specifically from the weakened status of planning. Perhaps ironically, during the years of sharp economic decline (the 1990s), the negative consequences of weak planning in many countries were partially offset by the fact that there was limited new building activity, as mentioned above. Thus, while the existing urban housing and infrastructure deteriorated, the sparse private resources invested in new construction guarded against the spread of poorly planned new building forms. This all changed about the year 2000, however, when economic growth picked up, leading to intense new construction in cities. The new construction did not always benefit the broader citizenry.

One obvious example of harmful new development is the loss of public green space. Socialist-era cities were generally more compact than their capitalist counterparts (Hirt, 2012). This is because the state controlled the periphery of cities, channeled the majority of the population toward the high-density mass-housing areas, and prevented sprawling suburban developments of the type common in capitalist contexts, especially in the United States. This changed dramatically after the end of socialism and specifically after the economic stabilization of the late 1990s. The outskirts of large cities were increasingly overtaken by upper- and upper-middle-class residential developments alongside big-box commercial establishments (malls, warehouses, business parks, entertainment complexes, etc.). Urban sprawl became one of the paradigmatic features of postsocialist urban development. The European Commission (2006) described cities in many East European countries (e.g., Bulgaria, Croatia, Estonia, Hungary, Latvia, Poland, Slovakia) as sprawling at rates far exceeding those in Western Europe. The Russian capital Moscow, for instance, lost 750 ha of forests in its once-lush greenbelt in just 2 years, from 1999 to 2001. During the same short-time period, forests in the metropolitan area decreased by 15% and grass areas declined by 55%, while impervious surface grew by 26% (Boentje and Blinnikov, 2007). The process of suburbanization, which devoured the once-compact edge of cities, was strengthened by the government fragmentation and decentralization that was instituted during the early postsocialist years. Although a welcome step toward a more democratic, 'closer to the people' government, the decentralization process created new institutional actors, small suburban-type governments, which in an era of scarcity competed vigorously to attract new taxes and economic development. The mechanisms they used to compete with their neighbors included making virgin land available for development, softening of building and zoning regulations, and adopting various incentives to attract large-scale developers. The outcomes of such policies are shown by Stanilov and Sykora (2012), for instance, the municipal competition contributed directly to the growth of sprawling developments in the vicinity of the Czech capital of Prague.

Loss of green space affected not only urban outskirts but also inner cities. Socialist-era regimes had demonstrated extraordinary generosity when it came to urban parks and neighborhood green spaces. This was because they had nearly full control over urban land, and because large public spaces well expressed the collectivist ideology of the socialist time period. But intense construction during the years of the post-socialist economy recovery devoured much of what may have been the most positive spatial legacy of the socialist years – the large public green spaces. In the Bulgarian capital of Sofia, for example, about 30% of public green spaces were 'lost in transition' and another 30% are awaiting the resolution of restitution claims (Hirt, 2012).

Another problem that may be attributed to weak planning during the postsocialist transition has been the loss of historic heritage. Although socialist-era regimes had maintained the landmark architecture in city centers, they had quietly left many historic neighborhoods to decay. Still, buildings in these neighborhoods were typically kept; i.e., they were not demolished and replaced with modern structures en masse as was the common case in some West European countries during the mid-1900s. Having survived decades of neglect, about the year 2000 historic areas in prime locations in East European cities were subjected to heavy market pressures. Developers were rarely interested in restoring the old structures. And whereas, in some cities and countries, the historic heritage laws were applied relatively stringently and demolitions were prevented, in others, especially those where growth pressures were immense, the laws were applied selectively thus allowing the destruction of invaluable historic buildings. Russia's St Petersburg, which is one of the largest UNESCO Heritage Sites in the world, is a well-known case (Trumbull, 2012). According to the local Architecture Preservation Society in the capital Moscow, some 400 buildings that were federally or locally designated as historic landmarks have been demolished since 1989 in order to make room for glitzy new developments (other experts put the number at 700; Hirt and Stanilov, 2009). And this count does not include the hundreds of other historic buildings that were not remarkable enough to make it into the official lists.

A fourth problem that planning failed to address is the change in mobility patterns. Socialist-era cities had fairly sophisticated mass-transit systems, which served the residents of their compact neighborhoods well. Following from the sprawl of the postsocialist metropolis and the limited investment in public infrastructure made in most countries, the urban citizenry became increasingly dependent on individual automobiles as the chief means of travel. In most East European countries, car ownership more than doubled during the postsocialist period; it is now rapidly increasing in the Caucasus region and Central Asia. For example, in Latvia, car ownership increased from 83 to 297 cars per 1000 people in about 20 years. Planners in this country's major cities, especially the capital of Riga, regard traffic congestion and air pollution as some of the worst current urban problems, yet little has been done to mitigate them. Auto-induced urban pollution has become an especially acute problem in the poorer countries, where much of the automobile stock comprises old second- and thirdhand cars imported from Western Europe, which do not meet contemporary emission standards (Hirt and Stanilov, 2009).

A fifth planning-related challenge stemmed from the sharpening stratification of postsocialist societies. Surely, urban planners and policy makers could have done little to prevent the yawning gap that developed between the handful of newly rich and the majority of the national populations during the first years of the postsocialist transition. However, in failing to produce an appropriate combination of policies, regulations and incentives to mitigate some of the negative outcomes of the postsocialist 'investor urbanism', planners contributed to converting social stratification into a spatial phenomenon. The socialist state had succeeded, albeit through authoritarian means, to reduce social segregation in cities. The mass-housing estates, specifically, were homes to wide and diverse segments of the population, from the intelligentsia to the working classes, and only the top regime apparatchiks lived in elite enclaves either in the centers of capital cities or in occasional securitized compounds at the urban edge. Assuming we consider spatial integration a positive phenomenon, we could say its benefits were all but lost in

postsocialist times. Middle and upper-middle-class residents of postsocialist cities have been increasingly exiting the mass-housing districts to settle either in the gentrifying neighborhoods of city centers or in the growing leafy suburbs. In some countries, the mass-housing areas are now occupied predominantly by elderly pensioners or ethnic minorities. In addition, in fast-growing cities, which attract residents from small towns and the countryside in search of jobs and services, the new peripheries very much resemble the type of slum areas found in the outskirts of the large cities of the developing world (e.g., Tsenkova, 2012). In the meantime, explicitly privatized urban forms, especially highly securitized gated communities, have gained popularity among new urban elites (e.g., Hirt, 2012).

The five planning-related challenges discussed above certainly do not comprise an exhaustive list. Many other serious urban spatial issues remain; for example, the need to adapt the extensive brownfields occupied by the derelict socialist-era industries to new use; the need to reconstruct the vast socialist-era housing stock, some of which is in perilously poor shape; and the need to deal with the poor quality of structures constructed during the lawless 1990s. These issues have been successfully addressed only in the most prosperous parts of the former Eastern Bloc: in the former East Germany and, to an extent, in the Central European states. However, there are signs that urban spatial planning is recovering from its crisis region wide and could, therefore, become more instrumental in solving some of the serious challenges. To begin with, the effects of chaotic urban development (congestion, pollution, etc.) of the 1990s have become so obvious that today there is a much broader political acceptance of planning as a legitimate municipal government function than there was a decade or two ago. Urban planning activities are definitely on the rise across the region. New master plans have by now been adopted for about every large city in the region; in many cases, the new master plans have in fact already undergone multiple revisions and amendments (Hirt and Stanilov, 2009). Alongside, the neighborhood-scale regulatory plans have been continuously updated and their implementation mechanisms have been strengthened, all of which sharply reduce the possibility of going back to the 1990s-style 'free-for-all' growth.

In addition, other types of planning are taking root as well. One new instrument is strategic spatial planning. Like master plans, strategic plans have a citywide focus. However, they are typically based on a shorter time span. Also, instead of attempting to address the full range of urban problems as master plans do, strategic plans aim to resolve only a specific set of pressing challenges. A 'typical' focus includes: improving city competitiveness in the era of globalization, fostering urban economic growth, promoting municipal financial reform, improving quality of life via modernizing housing and infrastructure, and enhancing urban sustainability (including through adopting local versions of Agenda 21). Many major cities in the region have by now passed strategic plans in addition to their traditional master plans (for example, Bratislava, Budapest, Prague, Riga, Sofia, Tallinn, Tirana, Zagreb). Because of their tangible focus, the strategic plans have attracted much wider interest from the citizenry than have traditional master plans. The second new type of planning is regional development planning. Regional plans are prepared by the regional layers of government created in the new member states of the European Union. They are essentially economic development plans, which the European Union requires in order to direct its massive structural funds. These funds aim to reduce regional disparities in income, wealth, and opportunities across the European Union and have been employed primarily in the new member states. The regional development plans do not necessarily have a spatial component. Still, in thinking through region-wide economic and other issues comprehensively, they have come to fill the planning vacuum that was created after the collapse of Soviet-style central economic planning. Finally, some planning activities have returned to the national level of government. Specifically, many countries have adopted national environmental strategies as well as action plans focused on specific environmental issues (e.g., air quality, water quality, biodiversity, waste disposal). This is especially true for the new European Union member states, which have been required to harmonize their national environmental legislation with European Union standards. Overall, whereas the era of virtually no planning in the transitional countries may be over, only time will tell whether the new planning activities will succeed in substantially improving the quality of life of the 400 million people who live in this part of the world.

Planning Ethics

Carlos N Silva, University of Lisbon, Lisbon, Portugal

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Planners and other professionals and officials in city government need to gain the confidence of the community they serve, and for that reason they must follow a standard of conduct that is far higher than what is strictly determined in the law. In order to achieve this, professional organizations in the multidisciplinary field of urban planning have adopted, in some cases as early as the beginning of the twentieth century, codes of professional conduct or codes of ethics. This article examines and discusses the different ethical perspectives that somehow frame the professional conduct of planners, explores a sample of these codes of ethics, its contents, and practical application, and identifies new challenges likely to result from the widespread use of information and communication technologies in the planning process.

Introduction

The main purpose of urban and regional planning is to pursue the interests of the community as a whole. However, with the increasingly diverse social and multicultural structure of our contemporary urban societies, that purpose is no longer as straightforward as it may have appeared in the past, since citizens with such highly different social and cultural backgrounds have potentially different and conflicting goals. In part for this reason, urban and regional planning is no longer seen as a politically neutral activity, contrary to the prevailing perspective during most of the twentieth century, namely within the framework of the rational planning paradigm. Planners and other professionals and officials in city government need to gain the confidence of the community they serve and for that reason he or she must commit to a standard of conduct that is far higher than what is strictly required by the planning law.

If in previous planning paradigms, from the City Beautiful and Garden City movement, at the end of nineteenth and early decades of the twentieth century, to the Congrès International d'Architecture Moderne discourse on Urbanism, or in the rational planning paradigm, urban planning was regarded as value free, this view was challenged since the late 1960s by postmodern approaches. This change was in part a recognition of the complex ethical dilemmas urban planners face in all stages of the planning process (Davey, 1996; Fox, 2000; Wachs, 1990; Younés and Paquot, 2000), related to the notion of public interest, obligations toward the community, colleagues, and employers to issues of intellectual property, privacy, confidentiality, as well as duties toward the environment, other forms of life, and future generations, and more recently also challenges associated with the extensive use of information and communication technologies, in particular the Internet, in the different stages of the planning process (Silva, 2010, 2012). Collaborative Planning (Healey, 1997) and New Urbanism (Silva, 2002) with their emphasis on citizen engagement in the planning process and in decision making highlight the importance of planners' values and the need to consider citizens' views and values as well.

In actual fact, planners face complex challenges in incorporating ethics into daily decisions over land uses, environmental conditions, social issues, and economic options, most of them multiscalar or multilevel, linking complex networks of actors, from the public and private sectors, in particular considering that an unethical conduct does not necessarily mean that it goes against the letter of the law, as Beatley (1994) and Perego (2010), among others, suggest. Despite that, and as the evidence shows, the discussion of these wider ethical issues within planning professional organizations is relatively recent (Hendler, 1990, 1991, 1999; Howe, 1990; Kaufman, 1990, 2001; Khakee and Dahlgren, 1990), including those basic professional issues normally dealt by the codes of ethics or codes of ethical conduct in the different professional organizations that make up the multidisciplinary field of urban planning (Fisher, 2000; Kaufman, 1990; Mahoney, 1992), as is recent the discussion (Howe and Kaufman, 1979, 1981) about the shift in the way ethical values were considered by planning professionals.

Nonetheless, some of these organizations, in North America, Europe, and in other parts of the world, adopted as early as the beginning of the twentieth century codes of professional conduct, which have been revised several times since then (Silva, 2005): in 1914, the American Society of Civil Engineers; in 1924, the International City/County Management Association (ICMA, 2004); in 1930, the Royal Town Planning Institute (RTPI); in 1962, the American Society of Planning Officials, the predecessor of the American Planning Association; and in 1971, the American Institute of Planners, the antecedent of the American Institute of Certified Planners (AICP). The European Council of Town Planners adopted, in 1985, guidelines for professional conduct (ECTP, 1985). The Canadian Institute of Planners approved a code of conduct in 1994. In Australia and New Zealand, in Brazil, South Africa, and India, there is also evidence of a similar process, to mention just a few more examples from other continents.

Ethical Issues in Urban Planning

Urban planners face three kinds of ethical issues (Silva, 2005). The first, related to individual rights, includes, for example, the

dilemmas associated with the choice of lifestyles and the preservation of the characteristics of a locality, paternalism, and the need to reduce damages. The second, related to social justice, includes obligations toward different social groups within the community, requiring planning decisions and actions to reduce economic and social inequalities, if necessary, through positive discrimination in favor of the most disadvantaged groups; in other words, a plan should reduce inequalities within the community, in part through positive discrimination in favor of the most vulnerable social groups, according to income, age, gender, ethnicity, and ability; in addition, planners have obligations toward future generations, since planning decisions, regarding the built environment and the natural patrimony, have far-reaching consequences. The third is related to the moral obligations planners face in relation to the environment and sustainable development.

Planning also has ethical duties toward other jurisdictions, since some of the issues it addresses are multiscalar by nature, requiring coordination with other subnational authorities, municipalities, and regional entities and transborder cooperation. This can be addressed by the creation of metropolitan or regional self-governments and institutionalized forms of transborder cooperation as is the case in some parts of the European Union. Transparency in the decision-making process is another ethical duty planners have, which requires nondiscrimination of social groups or individuals and the proactive inclusion of all those usually excluded from the public decision making, providing a fair participatory framework.

In sum, faced with the urban transition, in which more than half the world population now live in urban areas (UN-Habitat, 2010), with the challenges of climate change (UN-Habitat, 2011), and 20 years after the 1992 Rio Conference, or 25 years after the 1987 Brundtland Report, planners have now an accrued moral obligation to plan sustainable and resilient cities and regions (UN-Habitat, 2009; UN, 2012; UN-ISDR, 2005).

Ethical Perspectives in Urban Planning

Planners, as happens with other practitioners, are guided in their professional activity by an ethical framework that is the result of multiple influences, reflecting the socialization process they went through during their lifetime. These influences include, for example, values and experiences within the family context, influences from the school, friends, religion (i.e., religions differ, among other aspects, according to the degree of their anthropocentrism), political influences, and professional experiences as well.

Ethical perspectives in planning can be grouped, as proposed by Beatley (1994), according to two main dimensions. The first opposes the consequentialist perspective, according to which it is the outcome of an action (i.e., the outcome of a plan, project, or planning decision) that determines if such an action or decision is correct or not (Beatley, 1994; Darwall, 2003a, 2003b) to the deontological perspective that sees an action or behavior as having a value in itself, worth fulfilling independently of its consequences. In other words, it is possible to have planning practices with an ends-oriented ethics and other practices more means oriented.

The second dimension reflects the importance given to the *Homo sapiens* in the definition of the moral community, and opposes the anthropocentric to the nonanthropocentric perspective. While for the anthropocentric perspective, the *H. sapiens* is the center or the sole member of the moral community, for the nonanthropocentric also other forms of life and the environment as a whole are included in the moral community, with a value intrinsic in themselves independently of the relevance they might have for human beings. Therefore, planners can have rather different professional practices as a result of their ethical perspective. This has been empirically substantiated in the pioneering works of Kaufman, Khakee, and Dahlgree, referred by Silva (2005), as well as in more recent studies.

The deontological and the nonanthropocentric perspectives are relatively recent within the planning profession, emerging partially in association with the overall critique to modernism and rational planning, on one side, and the rise of the sustainable development agenda since the late 1980s, as argued before (Silva, 2005), and more recently also associated with the discourse on resilient urban development. From this perspective – deontological and nonanthropocentric – urban planning seeks to maximize the public interest without putting into question other moral duties in relation to other forms of life, as well as toward the creation of a more just city, in the sense Fainstein (2010) and Soja (2010), among others, put it, or more generally, a more just society.

A new ethical perspective seems necessary, if urban planning is to meet its obligations toward the preservation of the environment, not only for the needs of the *H. sapiens*, but also for other forms of life and future generations. Urban planners have an ethical duty to minimize the ecological footprint of cities, which requires a more compact urban form, the redevelopment of brown-field areas, higher densities, and a social and functional mix as well. In that sense, the United Nations sustainable development discourse, recently reinforced in the Rio+20 Conference (UN, 2012), and the New Urbanism plea for a more compact city and smart growth instead of continued urban sprawl, more pedestrian-friendly areas, biodiversity, and natural habitats protection, are just examples of some of the new ideas that contribute toward a more ethically responsible urban planning.

Planning Ethics in the Codes of Professional Organizations

In part as a consequence of these changes, it is now common for professional organizations of planners to have a statement of ethical principles or an enforceable code of professional conduct with the general purpose to set standards, values, and behaviors in the different stages of the planning process. It not only sets an ideal for the profession and its core values, but it can also act as a self-regulation reference and serve as a guide of ethical conduct to its members. It informs the community, employers, and clients, about the values and obligations a planner is committed to, and reinforces the position or status of the planning profession within the society

(Hendler, 1990, 1991; Kaufman, 1990, 2001). Planners are expected to adhere to these rules or guidelines and to practice the profession with the highest professional standard in order to gain the respect and trust of the community where they work and which they are supposed to serve.

The exact content of these codes of ethics or ethical guidelines vary greatly among professional organizations but it is common for these codes and guidelines to require members, for example, to promote equality of opportunity and to prohibit discrimination on the grounds of gender, age, race, religion, disability, sexual orientation, or any other social characteristic.

Even though general ethics courses and ethics codes from other professional organizations can also be useful for planners, there are certain ethical issues that are specific to professional planners and, for that reason, the demand for training on the ethical issues planners are likely to face during the planning process increased and it is now common for planning conferences to include sessions on ethics, in which planning professionals and ethics experts share personal experiences and discuss ethical scenarios.

Certified planners are expected to follow the professional code of conduct and may be held accountable to it. Members not in compliance with the Code of Ethics and Professional Conduct may be subject to sanctions, including the loss of membership in the most severe cases. For other professionals working in planning, be they public decision makers or advisors, it may be enough to have just a statement of ethical principles in planning that will serve as a guide. For example, the Association of American Planners' (APA) ethical guidelines are supposed to be adopted and followed by anyone working in planning, from planners, in both private and public sector, to appointed and elected officials, and citizen as well. On the contrary, only certified planners are held accountable to the AICP Code, although other planning professionals should also take it into consideration.

The APA adopted a 'Statement of Ethical Principles,' in 1987, replacing the 1962 code of the American Society of Planning Officials, followed, in 1992, by a new and revised 'Statement of Ethical Principles in Planning' (Barrett, 2001; Kaufman, 1990; Lucy, 1997). The 1992 statement, still applied two decades afterward, was adopted as "a guide to ethical conduct for all who participate in the process of planning as advisors, advocates, and decision makers. It presents a set of principles to be held in common by certified planners, other practicing planners, appointed and elected officials, and others who participate in the process of planning" (APA, 1992). This guide is organized into three main sections: the planning process must continuously pursue and faithfully serve the public interest; planning process participants continuously strive to achieve high standards of integrity and proficiency so that public respect for the planning process will be maintained; and APA members who are practicing planners continuously pursue improvement in their planning competence as well as in the development of peers and aspiring planners. They recognize that enhancement of planning as a profession leads to greater public respect for the planning process and thus serves the public interest.

Its twin organization, the AICP, adopted a code in 1978 (the AICP Code of Ethics and Professional Conduct), replacing the 1971 code of the preceding organization, the American Institute of Planners. In 2000, the AICP started the revision of the 1978 Code, a process that lead, after numerous meetings, to the new 'Code of Ethics and Professional Conduct,' which went into effect in 2005, being revised in 2009 (AICP, 2009). It is not an entirely new code but introduced a number of important changes, both in substance and in the procedures. For example, the previous advisory rulings that have been issued over the years, since 1978, and which became an addendum to the previous code, were incorporated into the main text of the 2005 Code. It is admitted that similar rulings may be adopted in the future as deemed necessary during the application of the present code.

The AICP Code of Ethics and Professional Conduct is divided into three main sections. The first section – Principles to Which We Aspire – contains the principles that constitute the ideals to which every member of the AICP is committed, which are grouped into three sections: responsibility to the public; responsibility to clients and employers; and responsibility to the profession and colleagues. The second section contains 26 rules of conduct that AICP members should adhere to, receiving sanctions if they fail to do so, the maximum of which is the loss of certification. The next two sections deal with different procedures, including those applied when planners are convicted of serious crimes.

As an example of the diversity of structures that can be found in the codes of ethics, the comparison between the AICP code, in the USA, with that of RTPI in the United Kingdom, provides a good illustration. The RTPI code of professional conduct, last amended in 2011, and effective since January 2012, includes 17 clauses, with requirements that are expected to guide the professional activities of every RTPI member and three annexes (Supplementary regulations; Relevant Bylaws; Disciplinary action) (RTPI, 2012a; RTPI, 2012b). According to this code, RTPI members "(a) shall act with competence, honesty and integrity; (b) shall fearlessly and impartially exercise their independent professional judgment to the best of their skill and understanding; (c) shall discharge their duty to their employers, clients, colleagues and others with due care and diligence in accordance with the provisions of the Code; (d) shall not discriminate on the grounds of race, sex, sexual orientation, creed, religion, disability or age and shall seek to eliminate such discrimination by others and to promote equality of opportunity; (e) shall not bring the profession or the Royal Town Planning Institute into disrepute." In addition, the RTPI adopted a set of procedures for investigating complaints against members and for taking disciplinary action. Among other aspects it set rules regarding the collection of preliminary material; formal investigation; findings that no breach of the Code of Professional Conduct has occurred; findings that a breach of the Code of Professional Conduct has occurred; suspension from membership; provision for appeal; and publicity of any findings of a breach of the Code.

In the Planning Institute of Australia' Code of Ethics and Professional Conduct, last revised in 2002 (PIA, 2002), the principle that 'a planner's responsibility to the community must take precedence over sectional interests' is implicit. It has two main sections, the first of which deals with the rules and

norms (professional standards; conflicts of interest; confidentiality and disclosure; true professional opinion; professional competence; marketing of services; fair competition), and the second with the procedures and penalties.

Besides planners, other professions directly engaged in urban and regional planning also adopted codes of ethics and professional conduct, such as geographers (AAG, 2009), architects (AIA, 2007), landscape architects (ASLA, 2006, 2009), civil engineers (ASCE, 2006), and sociologists (ASA, 1999). These codes, as those of professional organizations of planners, mentioned before, are mainly focused on issues of professional conduct. All these professional organizations seem to agree that a code of ethics is far from being enough. The profession may have a good reputation, but if there are occasional ethical lapses, the good reputation can soon disappear. It is therefore imperative to build a professional ethical culture, which although not as visible as other actions, seems to pay dividends in the long term, both for the profession and for the community every planner is expected to serve. For that, the ethical foundations of the planning professional organization need constant attention and training during the entire professional life of its members. It is important to share stories about specific ethical issues planners' face, to learn from each other, building gradually an ethical culture within the profession.

For this reason, planning organizations tend to include ethical issues in their professional development programs. In case of AICP–APA, a toolkit was prepared to assist their local chapters in the organization of training sessions on the standards of planning ethics, a tool focused on themes that are eligible for AICP certification maintenance credits. These training sessions can have different formats according to the needs of the audience: lectures; panel discussions; facilitated sessions; and plenary sessions (AICP, 2010). Another resource made available for planners by their professional organization is a confidential telephone counseling service, as the one offered by the Planning Institute of Australia, when new ethical issues or dilemmas do not fit or seem not to fit well into the written guidelines and rules. The publication of short texts or research articles on numerous topics relevant to ethical practice in the workplace, as well as questions on ethics that have been raised by members of the professional association, and the staff answers based on the Code of Ethics, has also been used to increase ethical awareness of planners. In sum, ethical education should not only be made an integral part of advanced undergraduate and graduate degrees, but also of development training programs promoted by planning professional organizations.

The widespread use of information and communication technologies in urban planning is gradually changing the way planners work and how they interact with citizens and other stakeholders (Silva, 2007, 2010). These changes raise new ethical issues, in particular in the context of the new possibilities offered by the Web 2.0 (Buchanan, 2012), in the use of online research methods (Suri and Patel, 2012), or the same kind of ethical issues with new configurations, for example, in the field of privacy and confidentiality. Even if we accept that it is only necessary to apply the basic ethical principles in the new digital setting in which e-Planning takes place, the codes of ethics of planning associations should include an explicit reference to it.

Conclusion

It is now common to admit that urban planning inevitably faces ethical dilemmas in all stages of the planning process, from the initial decision up to the implementation and revision of a given plan, to mention just few different contexts in which ethical issues, interests, and values emerge and need to be addressed by urban planners. Simultaneous with this increasingly greater awareness of ethical issues, new ethical concerns related to human rights, social cohesion, a deeper green consciousness, as well as new challenges associated with the widespread use of information and communication technologies in the planning process, emerged in the field of urban and regional planning in the last decades. All this and the increased emphasis on sustainable development and urban resilience seem to be moving urban planning toward a more deontological and nonanthropocentric ethical perspective, although in practice planning decisions seem to continue being predominantly based on utilitarian and anthropocentric principles.

Abstract

There is a growing use of sustainable development by planners. The concept is being adopted without much controversy to create more holistic planning frameworks and community-based planning processes. However, there is no clear agreement on what sustainability means in terms of city size, urban form, and transportation. The debates are summarized and some resolution suggested.

'Sustainable development' or 'sustainability' for short simply means that in a global context any economic or social development should improve and not harm the environment. This concept has developed from a global political process over the last three decades of the twentieth century into one that now touches every part of society. Sustainability has cut across all disciplines and professions, and has developed many complexities in relation to how people plan for their futures (Pezzoli, 1997). Its application to planning is full of interest and controversy.

Town and regional planning has its origins firmly in a desire to improve the environment and create a better future. The visions of Ebenezer Howard, Patrick Geddes, and Lewis Mumford, for example, were all rooted in the need to make a greener city. Today there are many planners who use sustainability to rationalize why they are planning the way they do. This article will try to clarify the ways that sustainability is shaping how planning is done, as well as the differences in the ways that planners relate to sustainable development.

The issues relating to sustainability that appear to be uniting planners are:

1. How necessary it is to use holistic planning frameworks; and
2. How planning processes must start with community/civil society perspectives.

The issues which appear to divide planners are:

1. How planners view the size of cities; and
2. How planners view density and car dependence.

Some resolution will be attempted on these issues.

The Concept of Sustainability

Sustainable development was defined by the Brundtland Commission in 1987 after they were given the task of resolving the apparent global conflict between development and the environment (WCED, 1987). They concluded that it is possible to develop the world in a way that improves the environment if:

1. High income nations see their responsibility to reduce their resource consumption with every new step in the development process;
2. Low income nations direct development to those who need it most as only then will population growth stabilize and misuse of natural resources begin to ease;
3. All nations need to see development as meeting community goals, thus development must be inherently a 'bottom up' process; and,
4. All professions and disciplines need to adjust to a more holistic, integrated approach if sustainability is to be converted into real change.

The thrust of this article is that, within the sustainable development framework of thinking, there are clear differences in what planners are suggesting sustainability means for cities. However, the overall situation cannot be seen as just a series of raging controversies, and indeed there are substantial areas of agreement.

The Agreements: Holistic Frameworks and New Planning Processes in the Age of Sustainability

Dyck (1998) suggests that sustainability is a concept which challenges prevailing planning theory because planning has emerged primarily from a modernist social context. In this perspective, modernism has associated growth or development with increased resource use, trickle-down economics, and 'expert-oriented' planning. Very few planners are, however, espousing a modernist view in the new millennium, and even the World Bank seems to agree with the basic conceptions of how sustainable development should now be viewed (Leitmann, 1999). In particular, the areas of emerging agreement are the need for new, more holistic planning frameworks and community-sensitive planning processes.

Holistic Frameworks

The principles of sustainability outlined above can be applied to cities, though the guidance on how this can be done was not very clear in Agenda 21 and other UN documents. It is probably true to say that the major environmental battles of the past were fought outside cities, but that awareness of the need to come back to cities is now recognized universally by environmentalists, government, and industry (United Nations Center for Human Settlements, 1996).

Anders (1991), in a global review of the sustainable cities movement, pointed out that "The sustainable cities movement seems united in its perception that the state of the environment

 http://dx.doi.org/10.1016/B978-0-08-097086-8.74025-6

demands action and that cities are an appropriate forum in which to act" (p. 17).

One of the strongest themes running through the literature on urban sustainability is that, to solve problems, planners need to view the city as an *ecosystem*. As Tjallingii (1991: p. 7) puts it: "The city is (now) conceived as a dynamic and complex ecosystem. This is not a metaphor, but a concept of a real city. The social, economic and cultural systems cannot escape the rules of abiotic and biotic nature. Guidelines for action will have to be geared to these rules."

The city is an open ecosystem, having inputs of energy and materials. The main environmental problems (and economic costs) are related to sustaining the growth of these inputs, and managing the increased outputs. By looking at the city as a whole and by analyzing the pathways along which energy and materials (and pollution) move, it is possible to begin to conceive of management systems and technologies which allow for the reintegration of natural processes, increasing the efficiency of resource use, the recycling of wastes as valuable materials, and the conservation of (and even production of) energy.

There may be ongoing academic debate about what constitutes sustainability and how it applies to cities (Slocombe, 1993; Mitlin and Satterthwaite, 1994), but what is clear is that many strategies and programs around the world have begun to apply such notions both for new development and for redevelopment of existing areas. Holistic frameworks such as the Extended Metabolism Model (Newman and Kenworthy, 1999), the Ecological Footprint (Wackernagel and Rees, 1996), and Local Environmental Action Planning (Leitmann, 1999) are all emerging as new planning frameworks.

Planning Processes

One of the strengths of the sustainability concept is that it is not a set of regulations or even highly definitive principles. Its principles need to be examined by every local community to see how they can be applied to create better long-term futures for their children. Thus planners at the local level have often found something of the reality of sustainability through the use of Local Agenda 21 Plans which have emerged as a tool for planning since the Rio conference (ICLEI, 1996, 1997; Selman, 1996). Over 2000 local governments have produced such plans. Others have adopted approaches based on sustainability indicators such as Sustainable Seattle (City of Seattle, 1993) or the Local Environmental Action Plan (Leitmann, 1999), and many are now using ICLEI's Cities for Climate Protection system as a guiding approach.

All these new processes stress that planning has moved beyond traditional approaches such as Impact Assessment or Strategic Planning based on trend projections and functional separation. They have in common a desire to plan from a community base, integrated with the goals of the market and other levels of government, including the new global agendas generated from Rio, Kyoto, and beyond.

The stories of hope emerging at a local level are rich and diverse when examined at the grass roots level (e.g., Pathways to Sustainability Conference, 1997; ICLEI, 1997). The reason for this is probably that at the local level it is possible for government more easily to make the huge steps in integrating the environmental, economic, and social, in order to make policy developments that are sustainable. They are also closer to concerned people, and more distant from the single-issue powerful lobbies such as the fossil fuel and road lobbies, who are so obvious in shaping national priorities (Korten, 1990, 1995).

The Disagreements: Application of Sustainability to City Size, Urban Form, and Transportation

The disagreements that are apparent among planners, who all profess to want more sustainable cities, are reducible to issues concerning urban form and transportation. They relate to the size of cities and to their density/car dependence.

City Size and Sustainability

Many planners subscribe to the view that, on environmental grounds (and other criteria), cities would be better if they were smaller (Troy, 1996; Morris, 1982). This is an old planning debate, for example, Fischer (1976) shows how optimum size cannot be found on any social or economic variable, but the debate has new currency in light of the current move to seek 'smart growth' and growth management. The desire to keep settlements small is seen by many to be a major part of what sustainability means.

The evidence from studies of settlements shows that as cities get larger they become more efficient in energy use per person and other critical sustainability variables (Newman and Kenworthy, 1999; Naess, 1993; Smith et al., 1998). This appears to be related to the economies of scale and density associated with bigger cities, which applies equally to technologies seen to be appropriate for sustainable development such as transit, recycling, or the new information industries. It does not mean, however, that larger cities do not reach capacity limits in terms of their airsheds and water systems. But it does mean that simple ideas of decanting people from big cities to smaller ones would not help to create a more sustainable global future.

The evidence suggests that smaller cities find the process of achieving efficiency in economic and resource terms harder than larger cities. The strong emotional appeal of 'smallness' to our age is not, however, without its basis. E.F. Schumacher's 'Small is Beautiful' approach, with its attack on modern gigantism, is still relevant as it suggests that all technology needs to be at an appropriate scale for the community that it is meant to be serving. Community-scale technology is emerging as communities begin to assert their roles – whether the technology is in villages in the Third World or modern large cities (Korten, 1990). The thrust of the New Urbanism and the 'urban village' movement is that communities need to be physically designed for and given infrastructure at the scale of the community, in cities both large and small (Calthorpe, 1993).

Density and Car Dependence

In cities across the world the issue of urban sprawl is firmly on the agenda. Associated with it are the issues of density and levels of car dependence, and hence traffic. In the USA in 1998,

240 local governments had antisprawl initiatives on their ballots, and reductions in traffic had become a top priority across the country. However, debate among planners on these issues shows little sign of resolution.

The divide continues to widen between those advocating more compact cities and transit-oriented reurbanization (e.g., Cervero, 1999; Whitelegg, 1993; Roseland, 1998; Newman and Kenworthy, 1999; Calthorpe, 1993; Elkin et al., 1991), and those advocating reduced densities and only technological changes to cars (e.g., Gordon and Richardson, 1989; Troy, 1996; Wachs and Crawford, 1991; Johnson, 1993). Another category of planners sit on the density/car dependence fence (e.g., Haughton and Hunter, 1994), while others see the problems but tend to avoid the planning implications in low density, car-dependent planning (e.g., Leitmann, 1999; World Bank, 1996; Stren et al., 1992).

The data on density and car dependence is very clear. All cities appear to lie on the negative exponential curve of density and gasoline per capita (Newman and Kenworthy, 1999). The same relationship is seen across cities, so that as density increases, per capita energy goes down, well beyond any income factors, for example, Manhattan uses 500% less energy per capita than the outer suburbs of New York. The mechanism is understood easily in terms of the relative ability to use different modes as distances between land uses spread out. It suggests that density is a powerful determinant of gasoline use, and hence if cities are to develop sustainably they should be facilitating reurbanization rather than new fringe development. Other planning studies have also shown over many decades the link between low urban density and a range of environmental problems (RERC, 1974; Berry et al., 1974).

Despite this kind of evidence there is a long tradition of planners seeing density as a problem (Newman and Kenworthy, 1989). Those planners advocating the benefits of sprawl who are associated with land or automobile lobbies can be discounted in debates about urban sustainability (STPP, 1994). However, there are many environmental planners who also adopt the benefits of low-density planning (e.g., Gordon, 1990; Todd and Tukel, 1981; Coates, 1981). This suggests that there may be a deeper issue in this debate; an issue that also lies behind the question of city size and sustainability.

Radberg (1995), when reviewing the form of cities required to achieve sustainability, described the rationale for a more compact city which can conserve energy. He then set out the form of a city for achieving green objectives that are 'related to the ecological perspective' for 'recycling and cultivation'; this city is 'greener, more ruralized, more spread out.' He therefore raised the questions: Is there a conflict between the low-energy city and the green city? Is there a fundamental conflict between the need to have more urban land for the green city in order to do local ecological processing, and a low-energy city with its need to minimize travel distances and hence have a frugal use of land?

The resolution of this issue as suggested by Radberg (1995) was to enable some parts of cities to be developed more intensely for reductions in energy, and other parts to be more reduced in their density so that 'greener' activities could occur there. The evidence, however, is that those planners who support the reduction of density are not able to accept that any density increases are worthwhile (e.g., Troy, 1996). On the other hand, studies of urban ecology innovations by Scheurer (1999), confirmed by Beatley (2000), found that there are no increases in ecological activity in low-density areas. Indeed, the best examples of urban ecology (recycling, solar design, storm water retention, permaculture …) occurred in denser developments, mostly in inner city areas where communities were able to create innovative experiments, or in intentional rural or urban-fringe communities. In the car-dependent suburbs urban ecology innovations are rare.

Newman and Kenworthy (1999) tried to resolve the issue of density and the green city. They suggest that green innovations can indeed occur anywhere in a city, although experiments may best be applied in rural areas, especially in places where rural population decline is occurring. However, the broader global sustainability agenda cannot be subsumed by this new rationale for density-lowering; cities need to reurbanize while conducting simultaneous improvements in urban ecology. They suggest that the difference in attitude between the two groups is as much due to confusion over where different approaches to sustainability should be employed. In simple terms, the city should be allowed to become more urban, and the countryside more rural, if the multiple goals of planning and sustainability are to be met.

A resolution of this issue may not occur while people still use the word 'sustainable' to describe extensions of low-density, car-based development (even if designed with New Urbanist principles). The strong emphasis on reductions in energy that is now associated with sustainability will probably mean that car-based development increasingly will have to be described using other words that are less demanding of their global contribution.

Planning Theory: The Good City and Its Governance

Patsy Healey, University of Newcastle, Newcastle, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This contribution reviews the discussion in the field of planning theory about the relation between cities, their governance, and planning interventions. It emphasizes the interaction between concepts about the nature, purpose, and method of planning; the context in which they have developed; and the practices at which they have been directed. It reviews changing ideas about the good city and about what constitutes good government, commenting on how concepts of place quality and governance capacity have coevolved. It then reviews three key themes in the planning field that have contributed to the development of these concepts: the relation between ideas and action, the interaction between the substance and process of planning ideas and interventions, and the transformative emphasis in planning theory. The piece concludes with a comment on the contribution of planning theory to transforming governance practices and enhancing place qualities.

During the twentieth century, the concept and practice of what variously is called town design, spatial planning, territorial management, and town and country planning has developed into a complex area of public policy. The theory informing this policy field has been the product of continual interaction among ideas about how to do planning, the experience of planning in practice, the intellectual context available to those thinking about planning, and the agenda of problems and opportunities that planning has been harnessed to address. Inherently, the planning enterprise is caught up in institutional contexts that shape its meaning, its material expression, and its consequences. This contribution illustrates the interaction between ideas about the nature, purpose, and method of planning; the context of their production; and the practices at which they have been directed.

Cities, Governance, and Planning

Few of the ideas about planning that evolved in the twentieth century in Europe and North America initially came out of academia. There was no significant academic infrastructure for the field until the last quarter of the twentieth century. The origins of twentieth-century planning ideas lay in the experience of rapidly urbanizing societies, and the perceptions of injustice, disorganization, and threats to human health and happiness, which urbanization seemed to bring. These perceptions promoted political movements, pressure group politics and expert evangelism, and attempted to transform city government to cope with the complexity of issues that arise in large cities. The focus of attention ranged from the neighborhood, the city, the region, the process of governance, and the overall organization of society. Two core ideas informed these otherwise-diffuse endeavors: first, that through appropriate governance action, it is possible to 'make a difference,' especially in making cities and societies more sustainable and just; and, second, that the spatiality of social processes and the qualities of place are important dimensions of well-being.

These two ideas have been developed in different ways, which are illustrated in the following sections, with the aim of highlighting both the situatedness of planning ideas and how their realization and impacts are highly dependent on the specifics of institutional milieux.

The Good City

In the early twentieth century, planning generally was understood as focused on cities, on how to manage the congested and sprawling consequences of the urbanization arising from industrialization and new transport technologies (Mumford, 1961). Throughout the century, there has been concern about the qualities of cities as living places, as aesthetic products, as business locales, and as biospheric relations. Theories of urban form and the arrangement of regional space dominated the discourses of city planning until at least the 1960s (Boyer, 1983; Hall, 1988). Protagonists, a mixture of campaigners and specialists in urban development (architects, engineers, and surveyors), battled over the relative merits of different forms. By the 1950s, most Western states had some form of urban planning and land use regulation embedded in their central and local government policy frameworks and competencies.

This success in institutionalizing the idea of city planning soon was overtaken by vigorous critiques of the predominant focus on urban form. Sociologists such as Herbert Gans in the United States argued that cities should be understood through the way people lived in them rather than through their physical form. Jane Jacobs, a fine observer of the way people used urban neighborhoods, argued against planners' ideas of demolishing old neighborhoods to replace them with modern buildings and the separation of living and working spaces. Regional economists and geographers challenged assumptions about the dynamics of urban growth embodied in the urban plans produced by architects, engineers, and surveyors. The emphasis of the earlier generation of town planners on achieving urban quality of life for the mass of the people was replaced by a concern with distributive justice and the 'socially just city.' This idea emphasized that the poor should not draw the short straw in the distribution of access to urban living space. By the 1970s, Marxist analysts had joined the debate. Manuel Castells showed, in a study of a French city, that the aim of urban planning to improve the quality of life was a mask behind

 http://dx.doi.org/10.1016/B978-0-08-097086-8.74027-X

which developers and business interests could pursue strategies for realizing land value gains (Castells, 1977). This critical story had resonance in other parts of Europe where urbanization was proceeding apace, producing substantial development gains to landowners and developers. It was echoed in examples of urban renewal in the United States (Fainstein and Fainstein, 1986).

As a consequence of this critique, coupled with a slowdown in the pace of urban growth, in Europe at least, the idea of large-scale comprehensive planning fell into disrepute in the West. Urban management practices focused on the fine grain, the neighborhood, the site, and the urban renewal area. Attention in the 1970s and 1980s turned to projects and mechanisms. The focus on the physical form of the city was displaced by ideas about appropriate planning processes. Architects, engineers, and surveyors were replaced as a source of expertise for planning by regional economists, policy analysts, and those specially trained as 'planners.' A critique developed that suggested that the whole idea of attempting to 'plan' such a complex phenomenon as a 'city' was oppressive to the multiple realities and possibilities of urban life. Instead of designing the future city as a whole, attention turned to transformative innovations.

By the end of the century, a new wave of interest in the quality of cities, rural areas, and urban regions was building up in policy arenas and among commentators on planning (see Sandercock, 1998). The pressure for this came in part from an increasing awareness of new economic and social realities. The recognition of the openness of urban economies to the dynamics of global economic forces raised widespread concern about how to 'position' cities and urban regions in a landscape of competing regions. Traditional models of self-contained, hierarchically ordered cities no longer seemed to capture the reality of the complex urban agglomerations appearing around the world (Graham and Marvin, 2001). Most influential of all were the ideas associated with the rise of a new environmental consciousness in the last quarter of the twentieth century. This brought with it conceptions of the limits that the natural environment placed on human actions and of the need to consider transgenerational impacts not just short-term ones.

This led to a wave of interest in the 'sustainable city' (UN-Habitat, 2009). For some, this meant minimizing adverse impacts on natural environments, linked to ideas about 'ecological footprints' of urban development, and conceptions of the 'carrying capacity' and 'footprints' of environmental systems. For others, it emphasized keeping cities compact and reducing the land take for urban development. Others enlarged the concept to integrate the concern with social justice to that of 'environmental sustainability.' A version of sustainability that combined the principles of minimizing ecological impacts with ways of continuing to promote economic development had become a strong theme in public policy in Europe by the twenty-first century. But these two dynamics do not coexist comfortably. Tensions exist with notions of social justice, the multicultural city, and fostering innovative plurality. The reawakened emphasis on urban futures in planning theory thus opened up a complex set of issues that have since been explored vigorously by planning academics. Key themes in this exploration have centered on what constitutes the 'just city' (Fainstein, 2010) and on the contribution of informal development processes to improving place qualities (Roy, 2005). By this time, experiences from Asia and Latin America were beginning to have a significant impact on planning ideas.

These ideas and debates about the quality of the 'good city' and the 'good environment' were shaped by the changing dynamics of urbanization processes. In turn, concepts from planning theory have influenced the practices of urban management. Planners' ideas have molded the restructuring of existing urban areas, the design of new towns and settlements, and residential neighborhood design. They have affected the form and location of transport projects. They have shaped the evolution of urban street scenes through the impact of land use regulations. These regulations in turn have influenced the way land and property values are distributed and property development processes have evolved. Planners' ideas achieved this impact by framing the organizing principles and discourses used by governments in developing policy frameworks and organizing competences for planning 'systems.' The organizing principles and discourses of one era become embedded in practices and can come to outlive their usefulness. By the turn of the millennium, in many parts of the world, 'planning' as practiced was identified as 'part of the problem' of governance processes that do not match the aspirations and challenges of contemporary cities and regions (UN-Habitat, 2009).

Good Government

For the protagonists of early twentieth-century city planning, the everyday business of politics and government was 'part of the problem.' They sought to show a way forward by striding out ahead with their plans and designs, apart from this messy world. By midcentury, an alternative idea had taken root. Planning was a way of 'doing government' itself. In Europe, socialist movements advanced the role of planning as an alternative to allocating resources through market processes. In the United States, planning was promoted as a way to improve the quality of local government. Clientelist practices were well-developed in many cities, with adverse consequences for both the efficiency and effectiveness of public policy. Bureaucratic management was no better, as 'playing by the rules' led to government actions that did not adapt to the dynamics of changing situations or local specificities. The way forward, strongly advocated in the University of Chicago School of Planning in the 1950s, was to adopt principles of scientific management. This involved articulating the goals of an organization and translating them, through systematic steps, into policy principles or objectives that individual officials could use as guides as they developed responses appropriate to specific situations. This powerful idea, with its focus on 'means-ends relationships,' was strongly linked to the promotion of democratic government. Officials could be held to account in relation to their performance in achieving an organization's goals, whereas the process of strategy-formation made these goals and their justification transparent to citizens (Faludi, 1973; Friedmann, 1987).

Initially, it was assumed that the work of 'policy planning' would take place in a world of technical experts, reporting to politicians (Dahl and Lindblom, 1953). As Western democracies became increasingly educated and

pluralistic, distributing power and knowledge ever more widely among business groups, pressure groups, and citizen mobilization movements, this position has been challenged. Concepts of strategy, of evaluation of policy ideas and performance in relation to objectives, and of the systematic link between policy and implementation had become deeply embedded in expectations of government behavior in the West by the end of the twentieth century.

At the core of the original idea of a 'rational planning process,' as it was often called in the 1960s and 1970s, was the view that governments, and their teams of experts, needed to be able to explain why a particular strategy was appropriate in a particular context, how it would be implemented and whether it had been implemented. This idea became linked to the development of ways to make strategic and policy plans, create techniques of evaluating alternative options, appraise the impacts of projects, develop indicators to evaluate performance, and attempt to model situations, for example, land use and transport interactions, to assess the likely impacts of different courses of action. All these practices are still in common use in twenty-first-century urban and regional government, providing a methodological toolkit for planning office staff and consultants.

These early ideas attracted criticism almost as soon as they were propounded. The overall approach was challenged as deeply instrumentalist – defining the purpose of government in terms of achieving specific objectives effectively. The methodologies drew on welfare economics, with its utilitarian assumptions. The approach assumed that policy ideas were translated into action in a linear way, from top to bottom of an organization or government system. It was seen to be overgeneralized, failing to consider the differences that might arise in different policy fields and in different institutional contexts. It handed power to the experts, as the early city planning ideas had done. Politicians, lobbyists, and citizens were pushed to the sidelines. In the 1950s, a famous study by Meyerson and Banfield (1955) in Chicago showed that local politicians were not prepared to accept the restraints on their actions that the rational policy-planning model implied. In the 1960s and 1970s, scholars such as Charles Lindblom, Amitai Etzioni, John Dyckman, and Richard Bolan began to show how contexts might limit how far a policy-driven planning practice might go. An alternative was to accept the increasingly pluralistic form of local politics, and to develop a local politics around competing plans, produced by different interest groups. This approach, promoted by Paul Davidoff, became known as advocacy planning (Davidoff, 1965). The experience of policy practice began to look less and less like a strategy-driven process. Instead, analysts noted that the content of policy seemed to be negotiated in the flow of action, rather than being set in advance.

By the late 1970s, planning theorists turned their attention to issues of policy 'failure' and implementation 'gaps,' following landmark studies by Aaron Wildavsky and others. Wildavsky's work looked more closely at the institutional context in which policy frameworks were articulated and the ways planners, understood as experts and government officials, went about their tasks. It identified the problems that arose in cases in which policy ideas were not sufficiently 'owned' or understood by politicians, or by other parts of public administration that controlled significant resources or regulatory powers. There were close parallels with work undertaken in business studies. This analysis highlighted the difficulty of promoting strategy-driven governance processes where other ways of 'doing governance' controlled the culture of local government. It also showed that field-level actors, officials, and experts working up the details of policies, or acting at the interface between officials and the clients of public administration, developed their own ways to understand policies and how they might be applied.

This led to a critique of the rational planning process as a top-down viewpoint, challenged by a bottom-up viewpoint of the actors on the ground (Barrett and Fudge, 1981). The linear model of the policy process increasingly was challenged by conceptions of policy development as an interactive process, continuously evolving over time and drawing in different actors at different stages. In this formulation, planning was no longer either outside government or imposed on governments in an attempt to transform their processes. It was caught up inside politics and governance processes. In the 1980s, a significant strand of work associated with John Forester, Charles Hoch, and Howell Baum, began to address questions of the way planners committed to progressive values operated in these ethically challenging situations. This development, which became known by the end of the twentieth century as 'communicative planning theory' (Innes, 1995), was underpinned by an epistemological shift, drawing on nonpositivist philosophy, particularly pragmatism and the social theory of Anthony Giddens and Jürgen Habermas.

This philosophical shift, which by the 2000s had become widespread in the social sciences, focused attention on the construction of meaning in social contexts. Policy development was presented less as a technical exercise in calculation and design, and more as a social process to articulate ways of thinking and ways of acting that could command support among a wide range of players in urban and regional contexts in which power was likely to be diffused in complex ways rather than concentrated in the hands of a single elite. Key scholars in the planning field drew on the interpretive tradition as it was evolving in policy analysis (Wagenaar, 2011). They focused on the potential of collaborative and participative forms of policy making that were arising in many contexts to address complex and contested environmental and social dilemmas (Hajer, 1995; Hajer and Wagenaar, 2003; Healey, 2006).

The interest in collaborative and participative governance practices was partly a response to the search for deepening democratic practices, and there are close links between this work and the wider development of the idea of deliberative democracy. The interest was promoted by a critique of the paternalist and bureaucratic practices into which government in Western countries seemed to have sunk. Some argued for an overall reduction in the burden of government. This neoliberal trajectory was challenged, however, by the advocates of more participative democracy, who sought to reduce the perceived gap between the worlds of politics and government and the worlds of citizens.

By the late 1990s, ideas about consensus-building practices and collaborative strategy formation, collected and consolidated by planning theorists, were being rapidly circulated

internationally to help fulfill in practical ways the ambitions of politicians and officials trying to move in new directions. In this context, the value of policy effectiveness embodied in the rational planning process was supplemented by a concern with building democratic culture (respectful and citizen-centered styles of governance). During the first decade of the twenty-first century, there was an explosion of research about, and critique of, collaborative policy-making practices. Meanwhile, other contributions within the broad areas of postpositivist philosophy and the analysis of complex systems were emphasizing the unpredictability of the way futures emerge, and therefore the need for flexible, innovative governance responses (Hillier, 2007). These two strands coalesced in increasing interest in work on network governance and the governance of complex adaptive systems (Sorensen and Torfing, 2007; Innes and Booher, 2010).

The Coevolution of Place Quality and Governance Capacity

A key issue in these vigorous debates about place governance was the nature of the institutional context in which such new practices could flourish and how far their promotion could induce changes in governance processes and cultures. These developments lead to an interest in the different experiences of strategic planning initiatives and neighborhood transformations, notably in comparative work in Europe (Moulaert, 2000; Salet et al., 2003; Healey, 2007). This work centered on the transformative dynamics of governance capacity building, and the interaction between the content of policy initiatives and the governance processes through which such initiatives are realized. There remains a tendency, however, for the discussion of what makes a 'good city' to proceed separately from that of 'good governance,' Some agencies such as the World Bank and the United Nations have articulated universal principles of good governance.

The insight from work in the planning field, however, suggests that such universal statements neglect the situated contingencies of particular localities. Both what are valued as 'good' place qualities and 'better' ways of doing governance work to promote their realization are rooted in specific histories and geographies. These institutional dynamics need to be understood if transformative initiatives are to have a chance of achieving at least some of their ambitions. It is also clear, especially from examples in former colonized territories, that formal 'planning systems' inherited from the past may be part of the problem undermining place qualities in particular places, impeding effective governance, and sustaining unjust and environmentally destructive practices (UN-Habitat, 2009).

Planning Theories in Context

The enterprise of planning is profoundly committed to changing the ways things are, to transforming realities, whether those of cities or their governance. It is inherently normative in its value orientation, infused with the belief that deliberately designed actions today can have beneficial impacts tomorrow. Those who reject the idea that this is desirable or possible – anarchists, extreme free marketeers, and cultural postmodernists – will reject the enterprise of planning. Yet the idea that, in democratic states, governments should have policies and should be judged on how effectively they follow them through, is one of the great inventions of the twentieth century. It is being carried forward vigorously into the next century. What is changing, however, are the conceptions of where policies should come from, how they should be focused, and who gets involved in their articulation and implementation. These days, it is not enough for policies to be designed by experts. The quality of government increasingly is judged by the way its policy formation attends to the multiple voices of complex societies; by its skill in recognizing the complexity of economic, social, and environmental dynamics; and by its appreciation of the specific realities of the way policy programs are realized.

The contribution of planning theory to this enterprise has been to focus on critical themes surrounding the challenge of transformative collective action aimed at enhancing place qualities and improving governance cultures and practices. Next, I discuss three such themes.

Ideas and Actions

The first challenge focuses on the relation of theory to practice. The history of planning thought shows the many ways in which planning ideas filter into the construction of concepts, goals, and norms that guide specific actions: (1) through advocacy and campaigning that affects popular perception and politicians' agendas, (2) through the design of planning systems and formal norms, (3) through the ways these are interpreted in administrative and legal arenas, (4) through the formulation of explicit strategic frameworks and the ways these get translated into routinely used concepts and norms, and (5) through the training of 'planners' and the professional organizations that bring 'planners' together. Through continual interaction with these worlds, planning ideas themselves are changed. The contribution of planning thought in the twentieth century has been its preparedness, however ineffectively it often is developed, to link together the philosophy of normative action, the social science of urban and regional dynamics, and the fine grain of the practices of urban and regional governance. The challenge has been to draw out the significant strategic processes of governance that affects the qualities of places and territories, as lived, experienced, and given identity in multiple social processes (Friedmann, 1987).

Substance and Process

The geographer Ed Soja (1989) has remarked that twentieth-century thought has had a peculiar difficulty in perceiving the impact of 'being in a place' and of the spatiality of social relations. The notion of the autonomous individual in a 'free society,' or the social group as a 'class' in relation to other social classes, has been much more dominant. Contemporary culture, however, notices all kinds of cleavages and fractures, and stresses the complex relations individuals may have with others. Grasping the significance of place and territory in these complex representations and relations, and developing governance processes in which to give them voice, is a major challenge for urban and regional politics and policy (Massey, 2005). In planning theory, there has long been a debate

about how to relate the 'substance' of policy to the 'process' of policy development, with theories being criticized for giving too much weight to one or the other.

A second challenge for planning theory is to contribute to the coevolution of the 'substance' and 'process' of place governance. This has major implications for institutional design – who contributes what, when, and where. It also has implications for the articulation of values. There were major debates in the mid-twentieth century about whether planning was 'value-free' or 'value-full.' If 'value-full' were the values about process (fair, just, rational) or about substance (achieving specific goals, e.g., aesthetically pleasing environments, quality of life for ordinary people, redressing the unequal distribution of resources and power)? By the turn of the century, process values had been extended to include qualities of knowledgeability, inclusion, empowerment, and respect to all citizens, while substance values were infused with ideas about environmental sustainability and social justice. If the substance and process of governance for complex territorial problems are seen to coevolve, then it must be expected that values, too, coevolve. Several planning theorists have emphasized the importance of processes of social learning in action. Donald Schon introduced the important idea of the skilled practitioner reflecting in action (Schon, 1983), and John Forester has produced a corpus of work about the way practitioners go about 'doing' planning work (Forester, 1999, 2009).

System Maintenance or Transformation

The third challenge in planning theory lies in the approach to social change. Behind any idea of the 'good city' or 'good government' is some model of the nature and dynamics of social organization. For some advocates of planning ideas, it is the model itself that needs change. For others, the model needs correction to make it work better. As John Friedmann argued in the 1960s, some planning ideas sought to maintain basic systems. Others aimed to transform them. At the time, he was contrasting the management needed to trouble-shoot in Western democracies with the transformations needed in illiberal Latin American dictatorships, newly experimenting with democracy. By the 1970s, he had become much more radical, demanding 'social transformation' in overurbanized capitalist societies, dominated by global corporations. His work has resonance in many places experiencing the massive urbanization processes under way by the 2000s (Friedmann, 1973, 2011).

Throughout the twentieth century, people have been attracted to the planning field through transformative idealism. In the second part of the century in Europe, the target of transformation was a form of capitalism that dominated life chances, structured the way urban and regional space was used and damaged environments across the globe. For many, it was a shock to discover that the 'planning systems' and 'planning practices' that actually evolved seemed deeply committed to maintaining the very practices that they had sought to challenge. Ideas about alternative ways of organizing society, however, come up against the reality of the dynamics of social change. In some periods of tumultuous social change, any kind of planning is an impossibility. In some periods of entrenched stability, similarly, there are few cracks of opportunity to mobilize to do things differently. Most of the time, most situations are somewhere in between. In the contemporary world of complex relationships and diffused power, change happens both through big events (e.g., the 1970s Organization of the Petroleum Exporting Countries oil crisis, the collapse of communism, the 1987 property crash, the rise to power of neoliberal governments, and the financial crash and subsequent recession from 2008) and through lots of small shifts and mobilization episodes. Planning processes can help these shifts along. Instead of making plans that are assumed to be predictions of what will happen, plan making becomes more of an activity of social mobilization, encouraging new ways of understanding situations and new practices. Strategy development in a world understood as emerging in an evolutionary way takes on more of the character of collective invention and risk-taking in trying to shape futures rather than the mid-twentieth-century assumption that government could command resources and control futures (Healey, 2007; de Roo and Silva, 2010; Hillier, 2011).

The Contribution of Planning Theory

These debates in the planning field provide rich resources for imagining, developing, and critiquing governance practices as they affect urban and regional dynamics in the twenty-first century. Formalized in the planning theory literature, they range from philosophical debate to analysis of systems and practices and discussion of the situation of 'doing planning work.' In addition to its normative commitments, the planning field needs to find ways to combine imaginative foresight to help people think about how to work toward alternative futures with an astute and multifaceted engagement with evolving practices.

There are many windows through which this engagement has developed. One is that of the 'planner,' working within specific contexts and trying to make things happen differently. This has been the key contribution of John Forester, whose work speaks sympathetically to planners in complex situations around the world. Another is a focus on governance practices. In recent years, this work has been linked closely with the disciplines of urban politics and urban and regional geography, exploring questions about the relation between politicians, political regimes, experts, and citizens, and the way planning strategies and tools have been used in particular institutional milieux. A third window has focused on understanding the design of governance systems. This has examined competencies, law, resource allocation systems, and appropriate expertise, the top-down levers of policy change, and how these interact with bottom-up interpretive practices. Much of this work has been informed by the search for ways of changing governance practices. A fourth window has concentrated on ideas about the good city and the good society, especially in relation to ideas of environmental sustainability and multicultural societies, and on how these ideas have worked out in practice. The critical challenge for the development of planning as an enterprise is to recognize that these different windows do not represent separate compartments of the planning field. They merely cast a more intense lens over a particular set of

relations. All the others are still there, and need to be recognized as present, even if not the focus of a particular study.

The role of planning theory, as a distinctive task in this complex and dynamic institutional terrain, is to provide a critical imagination and structuring ideas for the dynamic invention processes that continually are unfolding in political communities in cities and regions. It should offer evaluative vocabularies for the recording and critiquing of these processes, both in relation to their content and their procedures. It should interpret emergent patterns and assess their consequences. It should draw in ideas from other fields and translate them in ways that are understandable to the various 'thought-worlds' caught up in city governance. It should consolidate the distinctive understanding evolved by engagement with this activity and make it available to those working in other fields. This implies that the task is always an in-between one. If the practitioners of planning theory withdraw too far from the worlds of those engaged in doing the planning, then they lose their capacity to record, shape, connect, and translate. If they stay too close to the doers, however, they are unable to see beyond what the doers themselves see, and therefore cannot add value to the work of doing. The challenge for planning theory in the twenty-first century is thus to enrich the evolution of public policy focused on place quality and to do this in a way that fosters the flow of ideas among the many arenas engaged in shaping urban and regional governance.

Plato (428 BCE – 347 BCE)

Abstract

Plato is one of the most influential figures in the development of European thought. This article provides a short biography, deals with the complexities of interpreting Plato, and covers the main areas of Platonic thought (ontology, epistemology, ethics, and politics) and the major Platonic doctrines (Dialectic, Theory of Forms, and Unwritten Doctrine).

Introduction

Plato was born in 428 or 427 BC in Athens amid the turmoil of the Peloponnesian War and at the end of the Golden Age of Athens. He witnessed the decline of Athenian power and the violent change of political systems from democracy to oligarchy and back. However, as the offspring of one of the noble families of Athens he was also privy to the remarkable cultural achievements of Greek culture. Before meeting Socrates he was already acquainted with Cratylus, a disciple of Heraclitus and is likely to have had an excellent education in music, gymnastics, and grammar. After the execution of Socrates in 399 BC Plato undertook several voyages; although the details are hazy, he probably traveled to Megara, Cyrene, Egypt, and Magna Graecia, meeting with philosophers and politicians. Most notably, Plato became involved with the Sicilian court. Even though his first trip to Syracuse in 388 BC turned into a disaster (with some sources claiming that Plato was sold as a slave and only freed by chance), he returned twice, in 366 and 361 BC, still hoping to establish a form of philosophical government, but finally failing to achieve this goal. He died in 348 or 347 BC after a lifetime of teaching and research.

After his first trip to Sicily, Plato founded what we now call the Academy in the grove of a local hero, Academos, close to Athens. And even though Plato's Academy was a well-respected place of teaching, learning, and living, it was not just a school in the narrow sense, but also an 'academic' research institute in mathematics, astronomy, philosophy, law, grammar, and other subjects; Aristotle being its most famous student. While the site was destroyed by Sulla in 84 BC (when he needed the wood of the olive trees to build siege weapons to take Athens) the idea of the Platonic School lived on through later antiquity and the academy was reestablished and staffed by Neoplatonic philosophers until Justinian I had it closed in AD 529 as a threat to Christianization.

In developing his philosophy Plato could draw on many different strands of thinking, most of which are represented directly in his dialogues through proponents of the particular school of thought. The Heracliteans offered the idea that everything is in flow, Parmenides and Zeno held the idea that Being is one and eternal, the Pythagoreans thought that everything is ordered through numerical structures, and Anaxagoras saw the mind or intellect as the foremost principle of Being. Plato's most profound and famous source of inspiration is, at the same time, the one hardest to track, because Socrates, although present in nearly all Platonic dialogues and protagonist in most, never produced any written testimony of his philosophy. And even if Socrates appears in the works of others (Aristophanes and Xenophon) as well, his original teachings are still a matter of debate. If we judge the *Apology* to be the Platonic work closest to representing the original Socrates, his main concern was indeed the search for wisdom (*sophia*) (see Section The Meaning of Philosophy).

Plato's intellectual horizon is however not restricted to philosophy in our narrow sense. He alludes to mysteries and cults, quotes Homer, other poets, and playwrights. His interest in mathematics also shows up throughout the dialogues, where he often uses mathematical examples to illustrate philosophical points. The close connection between mathematics and philosophy is also echoed by the characters within the dialogues, as one of the most gifted interlocutors is the young Theaetetus, a friend of Plato and an eminent mathematician.

Another major influence on Plato's work is sophism. The term 'sophist' applied to a very diverse set of people, ranging from sages and scholars to lawyers and what we would call management consultants. They would offer practical education for certain fees, specializing in rhetoric and everything necessary for a successful career in politics. Plato's philosophy can be understood to a large extent as a reaction to sophism, especially its relativism (naturalism being the other opponent). Many sophists regarded truth and values as something merely relative, something to be negotiated by skilled orators depending on the occasion. Against this Plato sought to establish absolute truths and values, unveiled and defended by rigorous philosophical enquiry. Accordingly, many of Plato's dialogues center on discussions between Socrates and the sophists – some friendly, some rather heated.

Alfred North Whitehead's famous dictum sums up Plato's influence beautifully: "The safest general characterization of the European philosophical tradition is that it consists of a series of footnotes to Plato. I do not mean the systematic scheme of thought which scholars have doubtfully extracted from his writings. I allude to the wealth of general ideas scattered through them. His personal endowments, his wide opportunities for experience at a great period of civilization, his inheritance of an intellectual tradition not yet stiffened by excessive systematization, have made his writings an inexhaustible mine of suggestion" (Whitehead, 1929: p. 39). Plato's importance stems not just from his theories, but from the fact that he set the field for Western philosophy. He influenced Neoplatonism, Christian theology, the philosophy of the Renaissance, and German Idealism (Fichte, Schelling, Hegel) and continues to influence even those who disagree with or ignore him.

Hermeneutical Complications

Even though Plato is one of the few writers of antiquity whose complete works we know, there is no straightforward way of telling 'what Plato thought on X' due to two facts. Firstly, Plato never wrote treatises but dialogues (and a few letters) and secondly, he offers a powerful critique of the written word as a medium of philosophy.

The Dialogues

Plato's works might have had the purpose of encouraging readers to engage with philosophy and visit the Academy, but they are not 'academic' in our narrow sense in that they are not treatises laying out the last word of the author. They are masterfully crafted, witty dialogues in which we encounter very different people talking and discussing many issues with one another, often straying from the original topic just to end up with a philosophical conundrum of one sort or the other. This form of presenting philosophy has several advantages, not the least, readability. It also draws attention toward the processual unfolding of thought and matters of philosophical performance, rhetoric, and style; terminology can be kept fluid and the reader is forced to form his own opinion on the matters discussed, thus making Plato's work an ideal entry point to philosophical discourse.

Which topics are discussed and what mistakes are being made in any given dialogue depends heavily on the cast and situation of the dialogue in question. If you are talking with an arrogant, obtuse anti-intellectual, the discussion probably would not go as well as with an interested, smart, and open-minded friend; and even debates between mutually acknowledged experts would not be free of errors. Importantly, the level of sophistication of the arguments rests on the intellectual capabilities of the interlocutors. Thus, Socrates might confront an opponent with a line of reasoning we easily unmask as faulty but which trips up his interlocutor nonetheless, while the mindful reader can pick up subtle clues leading to the solution of a problem. Moreover, Socrates might discuss the same issue with someone else in another dialogue and come up with very different theses. Sometimes, Socrates explicitly chooses to withhold certain ideas due to lack of understanding on the side of his partner. However, the fact that Plato depicts shifty rhetoric, false reasoning, and omission of information does not allow us to conclude his own reasoning to be faulty or incomplete.

Also noteworthy is his steady usage of myths in the dialogues, which pose difficult puzzles of their own, due to the fact that they often stand in for their exact opposite, that is, logical explication.

Critique of Writing

Interpretation is further complicated by Plato's critique of writing. In the *Phaedrus*, Socrates explains why the written text in general is an inadequate medium for philosophy as it cannot explain and elucidate itself but always says the same; it is unable to decide who to impart information upon and it cannot defend itself. Text is dead, and can only ever function as an aid to memory (Pheadrus 275). This does not just sound unfamiliar to someone used to academic communication in the form of books and journals, but it also poses a conundrum for the interpreter. Does Plato's critique encompass all writing, even his own? If so, can we take it seriously insofar as it is presented in a dialogue obviously written with a reader, not a listener in mind? The passage itself makes no exceptions to any form of text so we are forced to assume that Plato considered his own written works as secondary. Until the nineteenth century it was indeed commonly accepted that Plato's main metaphysical doctrine was unwritten or only hinted at in the dialogues, but nonetheless taught, discussed, and passed down in the Academy. Many sources, including Aristotle, support this view. The unwillingness to acknowledge an unwritten doctrine behind and beyond the dialogues stems from a strand of romanticist philology centered around certain hermeneutical ideas on the infinity of interpretation and the urge to free Plato's thought from a (misconceived) notion of esotericism.

These hermeneutical complications lead to an interestingly wide range of contemporary readings of Plato, focusing on very different aspects of his work and based on very different premises. Yet, even though we should be cautious of attributing theorems to Plato, we can nevertheless identify certain recurring themes and ideas that seem to be basic parts of his thought, regardless of our specific interpretative background.

The Meaning of Philosophy

Wisdom (*sophia*) is opposed to folly (*amathia*), ignorance of one's own epistemic limits. The love or search for wisdom is thus first of all a critical undertaking during which the philosopher questions his own beliefs and practices as well as those of his fellow human beings. Socrates describes himself as the barb or fly (*myops*) that keeps the noble but lazy horse Athens awake with these kinds of investigations (Apology 30). He strolls around Athens examining the knowledge claims of politicians, artists, and artisans, asking for justification and explanation (*logon didonai*), exposing their ignorance by leading them into *aporia*, "paralysing them like an electric ray" (Meno 80). How the interlocutor reacts to such a shocking *reductio ad absurdum* – with angry rejection or interest – shows whether he is philosopher-material or not. An important step in the search for wisdom is to admit one's ignorance and indeed this is the only epistemic advantage Socrates primarily makes a claim on: "He does not assume to know something where he really doesn't" (Apology 21) and "trusts the expert rather than the public opinion" (Crito 43).

Yet philosophy is not merely a negative or skeptical undertaking, quite the contrary. To avert epistemic overreach one needs to reflect on the nature and criteria for knowledge (*episteme*) as against mere traditional belief (*doxa*) and the way (*methodos*) of transforming the latter into the former (Meno 75); one aspect of philosophy is thus epistemology, the quest for the knowledge of (the nature of) knowledge (Charmides 169). The movement from belief to doubt to reflection to understanding and so forth is illustrated by the dramatic form of the dialogues.

This concern with epistemological and methodological matters (Politicus 286) sets Plato's philosophy apart from

what came before, and it also sets philosophy as a whole apart from other epistemic enterprises, such as mathematics. Plato never disputes the effectiveness or methodological autonomy of mathematics, but he draws attention to the fact that mathematics qua mathematics cannot found itself. For while the mathematician proceeds deductively from axioms, he is not able to answer certain questions regarding his presuppositions (Politeia 510), like "What is the ontological status of mathematical objects?" or "How can concrete signs represent abstract entities?" or – more generally – "What is knowledge?" (Theaetetus 145). Only philosophical reflection (as against mathematical deduction or empirical induction) catches up with its own preconditions and proceeds to the unconditioned, that is, the Absolute (see Section The Unwritten Doctrine). Thus, Plato introduces the idea of philosophy as a presuppositionless inquiry.

Finally, doing philosophy means learning to die. Death is the final separation of body and soul, an event during which the true human sheds the mortal hull in which it is entombed (Pheado 82) or by which it is encrusted like the statue of a sea-god is encrusted in clams (Politeia 611) – a separation the philosopher already seeks in life as he strives to use his mind without being affected by bodily urges or dominated by the lower, feral, and illogical parts of his soul. For Plato, philosophy ultimately is care for the soul through which we achieve an existence ordered and led by reason; philosophy brings us closer to the 'likeness to god,' that is, absolute rationality (Theaetetus 176). Therefore philosophy for Plato is never just a theoretical affair, but a thoroughly practical, life-encompassing matter.

Dialectic and the Forms

Philosophy proceeds first and foremost by talking (*dialegesthai*), thus the method of philosophy is aptly named 'the art of talking,' that is, 'dialectic.' A philosophical dialogue is not a rhetorical match – its aim is understanding, not winning (Gorgias 454); the first dialectical virtue is therefore the ability to properly raise and answer questions (Cratylus 390) in a way the interlocutor understands (Meno 75). Philosophical discourse tries to answer essential questions, so the second dialectical virtue is the ability to find the essential features of the issue in question (Politeia 534) by distinguishing (*diairesis*) genus and species (Phaedrus 265; Sophist 253). The third dialectical virtue concerns the attitude toward (pre)suppositions. The philosopher tries to explicate his presuppositions and consciously posits a thesis to see how far it carries and how firm it stands; if the thesis comes under attack, he will revert to a higher, more abstract thesis founding the initial thesis (Pheado 101). The goal is to reach an ultimate position, from which no further enquiry is possible.

Dialectic aims at uncovering what is. But what is cannot be grasped with the senses (Phaedo 78), as everything sensible is necessarily in a (Heraclitean) state of flux. The true objects of understanding and knowing are not individual things but their Forms (*morphe*) or Ideas (*idea*/*eidos*). When we see a table we see a steadily changing thing, yet we understand the table as table, that is, we do not just stare at a heap of matter but we grasp the general meaning 'table,' the table-ness of this particular table, so to speak. We understand the thing in front of us as partaking in the Idea of the table. This idea or form is also what the artisan has in mind while fabricating a thing; for when this breaks he will remake it not looking at the broken thing but at the idea of it (Cratylus 389). Similarly, with mathematics, the mathematician does not care about the chalk figure on the blackboard but about the abstract entity of a triangle. The same holds for philosophy. The philosopher is not interested in concrete instances of, say, virtue but he wants to identify its essence. Often Socrates' interlocutor runs into difficulties because he does not grasp the difference between Idea and example, naming examples, but failing to offer an essential definition. The theory of Forms thus functions first and foremost as a corrective, leading the partners of the dialogue away from the all-too-concrete toward more general notions as the true prize of dialectical enquiry.

Ontology

The theory of Forms is often taken as a variety of realism, a misinterpretation going back to Aristotle. According to this view Plato envisaged two realms, one 'down here,' full of sad and meager copies of the Ideas in the other realm 'up there'; in the heaven of Forms we find ideal entities, perfect horses on perfect lawns, perfect beds in perfect bedrooms, etc. This, of course, neither makes any sense nor is it endorsed by Plato. In some sense, the Form of X is indeed X; the Idea of the table is certainly table-y in the highest sense, the epitome of table-ness. On the other hand, it certainly is not a real table, as a table is made of some material and can be destroyed, occupies a position in space time, owns a definite number of legs, etc. The idea of the table is not made of any material, it cannot be destroyed and cannot possibly be located somewhere with a definite number of legs as that would exclude it functioning as the Form for all tables everywhere with every number of legs; Forms are 'one above many' (*hen epi pollon*). The term 'realism' is a complete misnomer as the Forms are not things (*res*) as Plato himself makes clear in the first half of the *Parmenides* – even if his talk of 'images,' 'copies,' and 'likenesses' invites these misunderstandings. At the same time, Plato's alternative is not some kind of nominalism – Platonic Ideas are not mere Lockean ideas either. They exist independently of us and our idea of table-ness is directed toward the Idea of table-ness and our concept of table is informed by the Form of the table; the Ideas are not identical with our thoughts (Parmenides 132).

Plato does however employ a descriptive dichotomy between being, and becoming, epitomized in the analogy of the line (Politeia 511). Imagine a line, split in two according to the golden ratio. The upper half represents being and the lower, becoming. The upper half is correlated to thought and the lower to perception. While actual tables can be perceived by the senses and are subject to change (becoming), the table Form is immutable (being) and can only be grasped in thought. The two halves are then again halved according to the golden ratio, whereby the two realms of being/thought and becoming/perceiving are further differentiated. The realm of being now includes Forms in the strict sense (at the highest section of the line) and mathematical objects (one rank below, but still located in the region of being); to the Ideas

corresponds *noesis* (i.e. immediate, non-discursive understanding), mathematical objects are grasped in *dianoia* (i.e., propositional understanding). The realm of becoming now consists of things and their copies (shadows, reflections, images, etc.). One part of Plato's critique of art relies on the low ontological standing of images (Politeia 595). Variations of this hierarchical ontology can be found throughout the dialogues.

At the very top of this hierarchy we find a set of highest Ideas (*megista gene*), forming a complex nexus of mutual participation (Sophist 254, Theaetetus 185). This set includes, for example, the Forms of Being, Identity, and Difference. All of these Forms partake in each other as well as themselves: All three Forms exist, that is, they partake in Being; all three Forms are also different from each other, yet identical with themselves, so they all partake in the Ideas of Identity and Difference. Everything partaking in one of them necessarily partakes in all others. And so the most abstract and fundamental Ideas intertwine, guaranteeing determinateness to each other and everything else.

The *Timaeus* finally offers a long monologue on cosmology, starting with the construction and ordering of the world by the godly *demiurge*, proceeding to the nature of materiality (*chora*) and the structure of matter, where Plato introduces the so-called Platonic Solids as the mathematical basis for the classical four elements.

Epistemology

Seeing that philosophy as dialectical enterprise relies on speech as the means for arriving at knowledge (*episteme*), Plato outlines at least a rudiment of logic as part of his wider epistemology (Sophist 263). A 'logos' is always about something; it is a concatenation of nouns and verbs disclosing something; it is true if it discloses what is the case and false if it does not. Plato also formulates an ontological version of the law of non-contradiction (Politeia 436; Theaetetus 165; Sophist 259).

Knowledge must always be logically present-able and defend-able (Politeia 534; Politicus 287); what you know you can put into words (Laches 190). A good criterion of whether someone knows anything is thus his ability to teach (Alcibiades 118). Another criterion is generality, as knowledge about anything implies a general understanding of some kind: If Io, the rhapsode, really knew that Homer is a good poet, he would be able to generally judge the quality of any poet in question (Io 531). The fact that Io lacks this ability disqualifies him from having knowledge. Generally, most people lack true knowledge, which is why one should never epistemically rely on the many, but only on designated experts (Alcibiades I 111). The most important difference between knowledge and mere belief or opinion, however, lies in the 'bonds' placed upon knowledge. While both knowledge and correct belief (*orthe doxa*) share the property of being true (Gorgias 454), knowledge is 'bound' by the chain (*desmos*) of reason (*logos*) (Meno 97). Despite this, Plato seems to oppose the definition of knowledge as justified ('bound') true belief, insofar as Theaetetus proposes exactly this definition in the eponymous dialogue but finds himself in an unresolved *aporia* at the end.

Knowledge is – like speech – always about something (Charmides 168). Plato now assumes a strict correspondence between the order of knowledge and the order of being. According to this onto–epistemological correlation only Being can possibly be an object of knowledge. Thus, technically, only mathematics and philosophy could yield true knowledge at all as they alone concern themselves with pure Forms and mathematical objects. Yet, only philosophy fulfills the strictest, final requirement of knowledge: presuppositionlessness. For Plato, everything below absolute knowledge is mere belief or a kind of technique (Politeia 511, 533). True knowledge is only obtained by *noesis*, acts of immediate, non-propositional, and non-discursive understanding.

Acquiring knowledge is described as a form of remembrance (*anamnesis*); as the myth goes, our eternal souls knew everything before being entombed in the body and all earthly knowledge is just reacquired (Meno 86; Phaedo 66; Phaedrus 247). It is still a matter of dispute as to how this myth is to be interpreted, whether Plato takes it to be literally true or whether he presents a theory of a priori knowledge in mythical form (or both).

Ethics and Politics

Taking his cue from the real Socrates, Plato's early dialogues largely deal with ethical issues. Socrates is pictured in conversation with friends and acquaintances, discussing matters of virtue, the good life, and education. He talks about courage with the old general Laches, prudence with the young and power-hungry Alcibiades, piety with the priest Euthyphron (who is on his way to sue his own father), friendship with the young Lysis and his friends, etc. Important questions include the nature of individual virtues, the problem of whether there are several distinct virtues or only one, and above all, the question of whether virtue can be taught, which he discusses in depth with the sophist Protagoras and the diplomat Meno in the dialogues of the same name. Experience seems to weigh in favor of the unteachability of virtue, as virtuous leaders and politicians are obviously unable to impart their virtue to their offspring (Protagoras 319), yet Socrates stays cautiously optimistic throughout the early dialogues and indeed develops a whole theory of education over large parts of the *Politeia*.

According to Plato, the human soul is made up of three parts (Politeia 440): (1) the desires, called 'the inner beast,' (2) the faculty of courage and decision, and (3) intellect or 'the inner man' (Politeia 588). A variation of this can be found in the *Phaedrus* where Socrates compares the soul to a chariot, lead by a charioteer, drawn by two horses, one good and obedient, and the other bad and wayward. To better understand the relationship between these parts, Socrates compares them to the castes of merchants and artisans, and warriors and leaders in a utopian city state (Politeia 368). Each part of the soul – and accordingly, each caste – has its own virtue (Politeia 442). The desires should be tempered and moderated (*sophosyne*), the faculty of courage should be brave (*andreia*), and the intellect should be wise (*sophia*); accordingly the merchants should not be greedy, the warriors should be brave, and the leaders should be wise. The overall property of a soul/state organized in this way is that of justice (*dikaiosyne*) insofar as every part does what it should

(Politeia 433). A virtuous (i.e., moderate, brave, wise, and just) soul/state is a unified, ordered soul/state: virtue is order (Gorgias 504). The task of politics is to mirror the inner order of the soul in the outer order of the city-state. A true politician makes his people better (Gorgias 517), and he threads and weaves together all lives and public activities into one ordered whole (Politicus 279). The best politician is the one not wanting the job because he does not seek power and finds his rewards elsewhere (Politeia 520). This leads to the theorem of the philosopher king: philosophers should become leaders or all leaders should start to philosophize, else the political future looks grim (Politeia 473). In the utopian *Politeia*, the form of the state is one of a benevolent dictatorship, where the post of king is held by highly educated men and women(!), selected purely on grounds of capability and merit.

Plato distinguishes three basic forms of governance: monarchy, oligarchy, and democracy (Politicus 302). All three forms come in a good and a bad version. Monarchy with a benevolent king is the best political order, tyranny the worst; a proper aristocracy is the second best, oligarchy the second worst; and democracy in both forms thus forms the middle ground. Book 8 of the *Politeia* offers a theory of (d)evolution of forms of governance corresponding to the (d)evolution of the individual soul. Regardless of the specific form of governance, the quality of political life is ultimately determined by the leaders having true knowledge instead of mere opinion (Politicus 293).

The ordering of the soul is the highest ethical goal; doing a crime is therefore much worse than becoming a victim, as criminal behavior upsets the inner order, while falling victim to a crime only concerns property or health, not the soul (Gorgias 469, 474). This is especially important seeing that Plato assumes the soul to be (partly) immortal (Phaedo 100) and its state to be the main factor determining heavenly punishment as well as future life (Politeia 612). Art can also perturb the order of the soul; next to the low ontological status this dangerous potency is the second reason for Plato's criticism of art.

Without virtues there is no good life, no happiness, nor are there any goods in the strict sense of the word as all things only gain their value through usage; property does not make anyone happy unless wisely used (Euthydemos 280), so wisdom alone is the source of values. This emphasis on intellect is essential to Platonic ethics. Virtue is not just order, but a form of understanding: it is impossible to act virtuously by chance, the ordered soul is a consciously ordered soul.

The Unwritten Doctrine

Although Plato himself deemed his theory of principles too important to be written down, many report its content, including such prominent figures as Aristotle, Sextus Empiricus, and the Neoplatonists. These written accounts of the unwritten doctrine allows us an 'esoteric' reading of the dialogues, giving meaning to many of the hints, winks, and deliberate gaps within Plato's writings, grounding the dialogical musings in a more systematic framework. And while the theory of principles is esoteric in that it was not shared with the public, it is quite easily put into words and hardly ever forgotten (Epistle 7, 344). In its core, it just states that the Good is the One, with the Many (also called the Indefinite Dyad) as its polar opposite.

The theory of principles discloses the ultimate ground and capstone of Plato's philosophy. Accordingly only a theoretical definition will grant an understanding of the unwritten doctrine; that is, only a complete grasp of Plato's theoretical edifice allows to fully conceive of the function of the principles. Yet, it is possible to offer a few clues as to the nature of the One and the Dyad. Plato seems to endorse a form of polar monism. The One is the highest principle, the pole toward which everything is orientated; it grants unity and therefore order – in the realm of Being as well as Becoming. The degree of unity determines the ontological rank of any entity, that is, unity orders the ontological hierarchy. The polar opposite of the One is the Many or the Indefinite Dyad. It is the principle of materiality, acting as the manifold upon which the One bestows order. Their interaction enables Being and Becoming. These very abstract structures recur on every level of Plato's philosophy: One virtue (justice) encompasses many virtues (moderation, courage, and wisdom); one Form determines many objects; one king rules many subjects, just as one part of the soul rules the others; and one man (Socrates) stands against the many (*hoi polloi*).

The principles are not entities, but above and below Being or Becoming, respectively. Within the dialogues, the principles take on different guises, most notably that of the Good, which grants Being and conceivability to everything and is 'beyond being' (Politeia 509). The One itself becomes thematic in the second half of the *Parmenides*, although it is not openly classified as a principle. Here the old Parmenides explicates dialectically why the One is no entity: taken in its absoluteness the One is literally nothing; it has no properties, no features, no Being, not even a name (Parmenides 141) – for if it were to have all these it would not remain purely and absolutely one. The polar opposite of the One likewise has no Being. As Indefinite Dyad the Many is an absolute multiplicity, yet instead of transcending being, it lacks being because it lacks unity. It is too diverse to be anything but nothing. In the guise of materiality (*chora*) it can only be grasped by "a kind of bastard-thought" (Timaeus 52).

Abstract

Play is a malleable, changeable phenomenon, in terms of cognition, practice, and communication. Play places people into realities that are multiplicities of possibility. This article describes issues of the framing of play as separate from mundane reality, and contrasts play to the playful attitude that erupts suddenly into the mundane. Play is understood as a way of organizing activity, rather than any particular content of activity. Play is implicated in the making of change, and through this to the presence of violence. The aspect of violence is suppressed when play is rationally and neatly framed off from mundane reality, as make-believe and fictive. Studies of cosmology indicate that when play is implicated in the creation of cosmos, its effects are felt throughout the functioning of the cosmos that comes into existence. Otherwise, cosmos is perceived as peripheral and subversive. Finally, game is considered as a variant of play, a metaphor that has enjoyed especial popularity during the twentieth century.

Malleable, flexible, fluid, uncertain, changeable – all are adjectives that are used to describe play, whether as a medium of cognition, practice, or communication. Play refers to a complex of universal phenomena among human beings that also are found among numerous animal species (Fagen 1981). All peoples, though they may not distinguish in semantic terms between play and other behavior, likely engage in playing as they shift into a conditional or subjunctive sense of being, one that opens toward a multiplicity of possibility. The mathematician and the theoretical physicist play during the process of shaping their ideas no less than children imagine, practice, and repeat their inventions in their play. Useful overviews of play phenomena are given in Spariosu (1989), ,Schwartz-man (1978) and Sutton-Smith (1997).

Despite its pervasive presence, play is perhaps the least concrete of phenomena and therefore one of the most difficult to define. Any useful definition of play highlights its multiplicity of potential experiences. The anthropologist, Bateson (1972) perceives play as paradoxical, in that it is and is not what it seems to be. The classicist Spariosu (1989) terms play, amphibolous, or going in two directions at once. In a succinct manner, the anthropologist, Droogers (1996) defines play as, 'the capacity to deal simultaneously and subjunctively with two or more ways of classifying reality.'

Play and Reality

There is an intimate relationship between play and reality because play is first and foremost experiential, whether personal or social, and reality does not exist without its experiencing. In the creation and practice of realities of play, the imagination is crucial. Without the cognitive, the capacity to imagine realities, there is no play, just as, without the practice of experience there is no reality.

Play raises to the fore issues of alternative realities, the role of these and other multiplicities in social and personal life, and their consequences for human cognition and practice. The cognitive perceptions of play enable persons to enter into alternative realities, and perhaps into the simultaneity of multiplicity. Cognition is related intrinsically to how realities of play are imagined and framed differently from other realities. The practice of play entails the sensuous embodiment of these alternative realities; and, so, the subjective experiencing of play from within these imagined contexts that offer a sense of release, freedom, exploration, and perhaps exhiliration. The communicative component suggests that these specialized contexts of play are able to comment on the social orders from which they arise, and to send these messages back as the participants in play return to the reality of nonplay. Therefore contexts of play are metacommunicative in their relationships to social order: play communicates to its participants not only *how* to play but how such playing relates to social order. That play is framed as imaginative and malleable, and that through these qualities it generates and conveys metamessages informing players as to how to relate to aspects of social order, makes play perhaps the most fruitful of contexts of socialization, both for children (Briggs 1998) and for adults.

Framing Play

Given that play constitutes domains that cognize, practice, and communicate the shaping of imagination, are these domains to be conceptualized as incisively distinct from domains of serious reality, of not-play? This is the implication of Bateson's highly influential theory of the framing of play which separates play lineally from the serious, or not-play. According to Bateson, the cognitive metamessage, 'This is play,' brings into existence the play frame which cleaves between the seriousness of everyday reality and the imaginings which are practiced within the frame. One may adduce from this not only that play comes into existence as a corollary of its framing but also that play, and the practice of its imaginative multiplicities of possibility, is located within the restrictions of its framing. Viewed from outside the frame, play is make-believe activity that in fact does not exist. Experienced from within the frame, play may well be utterly engrossing in the embracing reality of its presence. These views accord well with Johann Huizinga's (1970) classic study of how civilization emerged through the

plastic premises of play; although in the process, play itself became a temporary sphere of make-believe activity, secluded, limited, and bounded in time and space. Once play is framed through lineal cognition, it becomes a world unto itself, one of temporary limited perfection with its own internal teleologies (Gadamer 1988). Within itself the practice of play may well proceed in deadly earnest.

Play and the Playful

Sutton-Smith (1997) offers a useful modification to the binarism of a reality either of play or of not-play, of make-believe or of serious reality. Sutton-Smith distinguishes between play and the playful. To build on his argument that the playful plays with the very framing of play itself, one can add that the playful is a mood, an attitude, that may permeate both serious reality and play, or that suddenly may surge into presence within the mundane. In either instance, the playful is full of the impulse to perceive and feel in ways other than those offered by the immediacy of a given reality. The abrupt presence of playfulness disrupts the most routine of expectations. Playfulness injects speedy uncertainty into the most expected of social practices.

The playful attitude within mundane reality may be integral to the existence and organization of the latter; while play itself may be more 'distant,' as it were, from mundane reality. Playfulness and play complement one another. The eruption of playful feeling and perception are a significant key to establishing the play frame in relationship to mundane reality. But the play frame itself directs the kinds of ludic or make-believe activities that take shape within it, relatively separated from mundane reality.

Play and Foundation-for-Form

In order for a play frame to come into existence there seems to be a need for a form of reference, a foundation-for-form or organic model that can be altered in systematic ways and turned into someone or something else. Nonetheless, whatever is changed retains crucial similarities to the form of its foundation and so remains intimately related to it. For example, The medieval European Feast of Fools which mocked the traditional Christian Mass needed the latter so that this could be inverted and altered. The play-mass, performed in church by priests, would have had no significance for participants were it not derived from and contrasted with its everyday analogue, the sacred Mass.

To take a more mundane example, when one little American girl, aged seven, turns to her sister, aged five, and says: 'Let's play sisters,' she is establishing a play frame within which these girls can play the foundational form of their sisterhood, imaginatively and perhaps with novelty. Play changes the known signs of form into something else by altering the reified boundaries that define and characterize the phenomenon. These girls will still be sisters, but they will be able to explore, practice, and experience their sisterhood with a difference, with license, in ways perhaps closed or unimagined within their usual relationship. They can play with the strangeness of being sisters. In turn, they may carry the messages of their experience back into their ongoing relationship as sisters, changing this in minute but additive ways. Hypothetically, they playfully may enter into play-sisterhood whenever they desire.

Attributes of Play

Play is a way of organizing activity, rather than any particular set or content of activities (Miller 1973). Any activity may be altered playfully, and played at. But in order to do this the everyday, instrumental perception of how means lead to and produce ends must be loosened, stretched, or perhaps uncoupled entirely. Goals exist in play, but the means to attain them are given degrees of autonomy. This is why play behavior can be endlessly repetitive or follow a crooked line around artificial obstacles. The patterning for play may be suggested by how the foundations-for-form that are used in playing function in the everyday. Say that the two little sisters and their friends place chairs in a row, the back of each facing the seat of the next, and that these children imagine these chairs to be a train. The children practice playing train, until they decide that the train is a plane, and the row sprouts wings, carrying its passengers, but then is turned into a bird flying off with children on its back, becoming a row of chairs in school and kindergarten that is also a plane. In each instance, one foundation for form (train, plane, bird) is imagined to take the place of another. Each such organic model is voluntarily turned into a foundation for imaginative practice that plays in turn with the multiplicity of these organic models, one after the other or as hybrids of one another (a row of chairs that with near simultaneity is train, plane, bird).

The perception and practice of play brings into being something that had not existed before in quite the same way. This is done by changing the shape and positioning of boundaries that categorize phenomena, thereby altering their meaning. Each shift by sisters into playing sisters seems like a repetition, yet is instead a different beginning since it imagines anew and plays with the very possibilities of sisterhood. Even a slight change in the boundaries that give shape and significance to phenomena involves some degree of destruction and recreation. In its cognition and feeling, play is associated closely with creativity, creation, and destruction.

Play is frequently implicated in the making of change. Change is the making of difference, even if this difference seems to mimic or eventually to reproduce an earlier state. Play introduces malleability into social and cultural life, taking apart the given and perhaps offering alternative visions and practices. Play often is involved in learning something new, through open-ended repetition, variation, exaggeration, and experimentation. Play is not unusual in the liminal phases of initiation rituals (Turner 1969), healing rituals (Kapferer 1983), and mortuary rituals of tribal peoples, when initiates, the ill, or the dead undergo profound transformations of being. Playfulness, in a more postmodern idiom is central to the practice of certain neo-shamanic rituals whose goal is the transformation of consciousness (Lindquist 1997). These and many other changing conditions involve shifts of cognition, practice, and communication. More significantly, change (creative or reproductive) usually involves fragmentation, destruction, or transformation of some sort, whether temporary or permanent, and these processes are often violent. The violence of change

and change through play are often closely related. Some form of destruction and violence (to cognition, feeling, body and being) is involved in the shattering suddenness of the playful and in play.

The Truth-Values of Play

The relationship between play and violence relates to how play has been conceived, and to the truth-values accorded to play. In his survey of philosophical ideas of play, Spariosu (1989) finds two trends, one that stresses the practice of play as prerational (with its roots in ancient Greek thought and poetry), and the other that emphasizes play as rational activity. In pre-rational thinking, play is full of violent agon and power, strongly and pleasurably emotional, arbitrary in its appearance, experienced perhaps as ecstatic, and opening toward unlimited freedom. In rational thinking, the naked, enjoyable forces of chaos and disorder, of irrational power and violence, are suppressed in favor of play as rationally framed activity that is set apart from serious reality. Here play is irreal in its irrationality, and therefore controlled, nonviolent, and limited in its freedom. To expand on Spariosu, one may add that the eruption of pre-rational play (akin to playfulness) into everyday life is full of its own unsuppressed truth-value. The truth-value of pre-rational play is integral to living within realities that overlap and that are continuous with one another – realities that relate to one another as multiplicities of possibility. By contrast, the make-believe status of rational play, framed and contained in special times and places (as Huizinga, Bateson, and others argue) denies any direct or immediate truth-value to play, enabling its practice to be treated as fictive, as 'just play,' 'mere play,' 'done only in play,' and so forth.

Play and Cosmology

The organization of cosmology demonstrates from another perspective the importance of the truth-values attributed to play. For example, in Indian cosmogen-esis, play (or more accurately, playfulness) is implicated in the very creation of cosmos. Thus, varieties of Hindu cosmology and religion embed premises of play – malleability, multiplicity, ongoing change – at a very high level of cosmic organization. In consequence, these self-same premises of play resonate throughout the levels of cosmos. The entirety of cosmos is influenced by premises of play. In this kind of cosmology, play is a top-down idea, responsible in no small degree for the multiplicities of reality that constitute Hindu cosmos and religions (Handelman 1992, Handelman and Shulman 1997).

Here play has high degrees of truth-value and is rarely referred to as make-believe. By contrast, mainstream monotheistic cosmologies, if they pay any attention at all to ideas of play, embed these at a low level of cosmic organization, distant from cosmogenesis and the ordering of religion and society. In monotheistic cosmologies, play is more of a bottom-up idea, lineally framed, rationally contained, and separated from serious reality. Bottom-up play enters cosmology and religion from their conceptual and emotional undergrowth, and therefore is perceived as threatening. Here the messages of play are often positioned in opposition to or as a negation of the order of things; and play is perceived as fantasy, illusion, and ephemeral; yet also as subversive and as resisting the order of things. But here the practice of play has low truth-value. Thus, the truth-value of top-down play is openly full of power and violence, while these qualities are veiled, hidden, and denatured in the low truth-values accorded to bottom-up play.

Game and Play

The idea and practice of game is closely related to that of play and may be understood as a variation of the latter, in the following senses. Game, like play, is a way of organizing activity. Game, too, loosens the relationship between means and ends. But the existence of game depends on relatively enduring rules, rather than on foundations-for-form that are easily changeable. Therefore games constitute distinct, autonomous realities, virtualities, given their internal, rule-based organization which to a high degree determines how they are practiced. Playfulness has less of a role in the practice of games. Games are less malleable and harder to alter than play.

Yet it is precisely because of their ruledness that games can be organized to make directed change through their practice. Levi-Strauss (1966) comments that game is a systematic way of creating inequality. Game begins with equality between its sides and produces differences which are perceived as significant. The logics of game, in fact, are often close to those of ritual which is intended to generate change through its operations. Traditional Mesoamerican ball-games had game-like aspects, yet they were ritual-like in their relationship between means and ends, perhaps ends of cosmic renewal that their practice was intended to accomplish. More generally, the presence of play and game within rites seem to contribute to the attainment of ritual goals. (This is powerfully exemplified in the roles of clowns in Native-American Pueblo rituals.)

Perhaps in more systemic ways than play, game may awaken interpretive, reflexive feelings about aspects of social and moral order. The highly agonistic Native-American Kwakiutl potlatch, a ritual full of conflict that both demonstrated and reordered social status, produced the 'play potlatch' (Codere 1956) in which participants laughed at their own strivings for power and hierarchy. The rigid gender divisions in traditional Iranian society produced games practiced by women in which these distinctions were called into question, mocked, and played with (Safa-Isfahani 1980).

The twentieth century has seen tremendous growth in the use of game as a metaphor for living and social order (Minnema 1998) – Wittgenstein's language games, Von Neumann's game theory, war games, educational games, the game of intelligence testing, games people play, the play of quantum mechanics, chaos theory, virtual realities, and so forth. In postmodernist terms, these visions are of life organized as interpenetrating games, none of which give any total or complete vision of reality, and no certainty about the stability of forms of living. The game metaphor reflects more fluid and mobile social orders that are perceived, correctly or incorrectly, as the creations of individual agency. Television as spectacle has contributed greatly to this growth by telecasting existing competitive game forms and aiding in the invention

of new ones. Sports are at the front of these developments. These multitudes of contest (in which violence is close to the social surface if not on it) continuously rank and re-rank participants over and again in hierarchies that are more kaleidoscopic, fragile, and ephemeral than they are enduring. Play as the multiplicities of possibility, and the playful as the eruption of these possibilities in the everyday, are competing with more unitary monotheistic ethoses, at least in the visions of the middle-class Western world.

Current thinking on play is reconceptualizing the problem of framing – the problem of relationships among realities, social and cognitive – to open alternatives to the ongoing rupture between play as rational and as irrational. Research on Internet chat groups plays into questions of framing (Danet et al. 1998). Issues of power in and through the practice of play are also related to questions of framing. Thus, ideas of 'dark play' (Schechner 1988), when players do not know that they are playing, and 'evil play,' when the manipulator of the frame positions herself outside it and plays others, yet pretends to be within the frame and controlled by it, relate to issues of play and power. They echo Bateson's still enduring thought that a more complex question to ask of a play phenomenon is whether it is indeed this, or whether it is pretending to be so. Imagining the pretense of play is even more powerful than play imagined as such.

Play During Infancy and Early Childhood: Cultural Similarities and Variations

Hui-Chin Hsu, University of Georgia, Athens, GA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Play is a common, yet complex, activity in infancy and early childhood across cultures. Cross-culturally, early play shows both similarities and differences. This article documents the coexistence of cultural-general patterns alongside cultural variations in the development (i.e., emergence and changes), varieties (e.g., object play and pretend play), structures (e.g., frequency and play partners), and functions (e.g., training and learning) of early play. Factors such as individual characteristics of the child and the caregiver, physical ecology, interpersonal context, cultural beliefs, and family immigration status that contribute to cultural variations are also reviewed.

Play is a common activity in infancy and early childhood across cultures. By nature, early play is complex, integrative, and characterized by developmental changes. Play during the relatively immature period of human development is believed to afford a low-cost and low-risk way for young children to learn about their environment for developing innovative and adaptive strategies (see Pellegrini, 2011). It is expected that play has both immediate and deferred benefits to children in multiple domains, including biological (e.g., signifying health and stimulating brain development), physical (e.g., exercising sensorimotor skills), cognitive (e.g., learning and creating knowledge), communication (e.g., making use of verbal and nonverbal skills), social (e.g., connecting and relating to others), emotional (e.g., expressing and regulating feelings), and motivational (e.g., initiating exploration) development. Early play also serves as an important socialization function to help young children learn cultural values to prepare for their adult roles.

Early play has been assumed to be a universal activity characterized by similar varieties and structures, following a similar developmental course, and promoting similar developmental skills across cultures. Converging evidence from anthropological and psychological research, however, suggests otherwise. A survey study (Singer et al., 2009) with mothers of children ages 1–12 from 16 countries in Africa, Asia, Europe, North America, and South America reported both similarities and differences in children's play. The cultural-general patterns shared between cultural communities included the following: playing outside was children's most enjoyable activity; children who resided in rural areas engaged in physical play more than those who resided in urban areas; boys engaged in more physical play than girls; and girls played more pretend than boys. Patterns indicating cultural diversity were also found; for example, children in the cultural communities with less advanced economic developments had higher rates of outdoor play than those in the cultural communities with more advanced economic developments; about half of the children played with toys; approximately a quarter of children engaged in pretend play; only children in Argentina, Ireland, Portugal, the United States, and the United Kingdom frequently participated in pretend play; and 15% of the mothers believed that pretend play was necessary for healthy development.

Taking a sociocultural approach, recent theorization challenges the universalists' view that early play is independent of culture. The socioculturalists' view suggests that play is not always valued across cultures, and that cultural variations are inherent in early play development. Early play is thought to reflect young children's experiences of growing up in a cultural setting. The regularities within settings, customs, and cultural belief systems organize children's developmental experiences and provide the information for children to construct their play. Through active practices in play, young children learn about their cultures (i.e., enculturation). Shaped by the specific cultural values and beliefs, early play is culturally determined and deeply rooted in daily routines and cultural practices (see Göncü and Gaskins, 2007).

Some developmentalists further argue that early play is not simply an outcome of a unidirectional influence that is passively shaped by the larger cultural beliefs systems. Rather, it is directly and indirectly influenced by a confluence of factors in a child's ecological niche. An ecological system view suggests that early play is a joint product of a multitude of distal and proximal influences, including biological and cognitive characteristics of the child, individual and behavioral characteristics of the parent, sociodemographics of the family, interpersonal experience, and the cultural context (see Bornstein et al., 2012; Bornstein's review in Göncü and Gaskins, 2007; Kenney, 2012; Haight et al., 1999). As a result of simultaneous interplay among these internal and external contributors, variations between individuals and across cultures are expected.

In this article, cultural-general (i.e., similarities) and cultural-specific (i.e., variations) patterns in the development, varieties, structures, and functions of play in infancy (the first year of life), toddlerhood (ages 1–2), and preschool age (ages 3–5) will be reviewed. Drawing on psychological and anthropological evidence, this article will discuss the factors contributing to cultural variations in early play by children and their play partners (e.g., mothers, fathers, siblings, and peers), including physical ecology and economic developments that determine the prevalence and varieties of play, interpersonal context that shapes cultural experience to be represented in play structures and themes, and cultural beliefs that influence the opportunities for and functions of play.

Play during Infancy

Caregivers across cultures engage in playful interactions and games with their infants during the first year of life. Both cultural-general and cultural-specific patterns are observed in person- and object-oriented play between caregivers and infants. Cultural-general patterns in the development of game playing, person-oriented play, and object-oriented play will be discussed first, which are followed by the reviews on cultural variations, including parental investment in play, stylistic preferences in play, play structures, and play partners.

Cultural-General Patterns

Similarities in Game Playing

When playing games with their infants, caregivers demonstrate cultural-general behavioral patterns. The majority of mother–infant games (e.g., peekaboo) are invariant and repetitive in structure, involving rhythmical motor actions coordinated with vocal and facial expressions to highlight the sequenced movements. Game vocalizations by mothers across cultures share the same distinctive features of elongation and fluctuation accompanied by exaggerated positive facial expressions and gestures. Perhaps such universal design of providing redundant information is an adaptation to the infant's developing attentional and cognitive abilities (see Fernald's review in MacDonald, 1993). Despite repetitions and regularities, caregivers also improvise with varying speed, melody, words, and gestures to make games highly variable and unpredictable. Further, caregivers in different cultures are sensitive to their infants' developing ability. In response to infants' developing motor skills, both European-American and Puerto Rican mothers not only increase game playing, but also offer age-appropriate physical support during play (Miller and Harwood, 2002). With age, the role of caregivers in game playing gradually changes from acting as a coach providing active scaffolding to infant, to acting as a playmate engaging in reciprocal play with infant, and to acting as a spectator allowing for greater infant participation.

Similarities in Person- and Object-Oriented Play

Mothers in different cultures demonstrate comparable contingent behavioral response during playful social interactions. During person-oriented play (e.g., kissing and face-to-face talk), despite unique cultural variations in specific behavioral channels (e.g., Kärtner et al., 2008; Keller et al., 2010), American, Chinese, Indian, Japanese, German, and Cameroon Nso mothers all contingently respond to their 3- to 5-month olds (see Bornstein's review in Göncü and Gaskins, 2007; Kärtner et al., 2008). By 3–4 months, infants across cultures begin to show an interest in objects at about the same time. To elicit properties and extract information about the objects, infants' play with objects similarly progresses from simple and spontaneous sensorimotor exploration (e.g., mouthing) to functional manipulation (e.g., rolling a ball). Mothers and their infants in different cultures are also similarly coordinated and attuned to one another during object-oriented play. Five-month-old American, French, and Japanese infants, for example, share the same preferences of looking more at the environment than at their mother and producing more vocalization than fusses/cries. Their mothers similarly demonstrate cultural-general patterns of responding to their 5-month olds' exploration of the environment with encouragement, to infants' nondistress vocalizations with imitation, and to infants' distress vocalizations with nurturance. Mothers are equally sensitive to infants' nondistress and distress vocalizations and make more frequent vocal response to infants' vocalizing than their looking (see Bornstein's review in Göncü and Gaskins, 2007).

Cultural Variations

Differences in Parental Investment in Play

Caregivers are motivated to invest in their infants' protection and provision in order to maximize their survival. Play requires time and energy and involves a commitment of resources. Play with infants is thus expected to be more common among cultures with high-investment reproductive strategies (see MacDonald, 1993). For example, games and person-oriented play between caregivers and infants are more common in foraging societies than other subsistence cultures because high-quality care is needed to ensure infant survival (Lancy, 2007). With greater exposures to hazards and predators, Aka hunter-gatherers in central Africa were more concerned about the survivals of their infants than their neighboring Ngandu farmers, and thus engaged in more promixal interaction (e.g., physical contact) and less distal communication (e.g., looking) with their infants (Hewlett et al., 1998; Lancy, 2007). By 9 months of age, compared to Aka infants, Ngandu infants engaged in significantly more object play and solitary play without caregivers' involvement. Cultural variations in caregiver–infant play can also be attributed to caregivers' adaptation to their ecological environments. Mothers of Kpelle in West Africa, Gusii in East Africa, Micronesian island of Fais, and American Navajo Indians rarely engage in playful face-to-face interaction with their infants (see Field et al., 1981). Their low-investment parental style may be due to the high infant mortality rate, as parental indifference may be a coping strategy to reduce the sense of loss (Lancy, 2007; see Rooparine's review in Pellegrini, 2011).

Differences in Appropriateness of Play

Play between infants and their caregivers can be regarded as an expression of broader cultural expectations and rules. Cultures differ considerably in their views about the value of play with infants. Parents in cultures where play is believed to be valuable for promoting cognitive or social skills (e.g., the United States and the United Kingdom) often engage in play with their infants. In contrast, parents in cultures (e.g., India, Guatemala, Nigeria, and Zambia) where play is for enjoyment, not promotion of development, rarely engage in play with their infants (see Roopnarine et al., 1994). In India, mothers do not see themselves as the playmate of their infant; yet relatives may assume the role of playmate for infants. In Italy, mothers regard play as inevitable, requiring no adult intervention (see New's review in Roopnarine et al., 1994). Appropriate play behaviors with infants vary widely according to cultural scripts. Kaluli mothers in Papua New Guinea describe their infants as helpless and they rarely utter to their infants, make eye contact, or elaborate utterances initiated by the infant.

Because verbalization is viewed as the primary indicator of competence, nonverbal vocalization is not interpreted as meaningful in Kaluli. Kaluli infants are not treated as a play or communicative partner, but rather as an addressee. Reflecting the socialization emphasis on social ties and cooperation, Kaluli mothers often face their infants outward to be seen by the larger social group and model how to appropriately use utterances for the infant to a third person (see Lancy's review in Göncü and Gaskins, 2007). Caregivers also follow culturally appropriate rules of expressing affect during play. Gusii mothers in southwestern Kenya avoid bringing out a high intensity of affect in infants during play, which reflects their cultural beliefs that unrestrained expression of negative affect produces apprehension and that masking feelings can maintain social order and minimize group diverseness (see Field et al., 1981). Because it is culturally inappropriate to display affection openly, East Indian mothers display low emotional expressivity during play with their infants (see Roopnarine's review in Pellegrini, 2011). On the other hand, the high values of interpersonal dependency in Indian culture may be expressed in the greater overlaps and shorter pauses between mothers' talks with their infants' vocalization (Gratier, 2003). Infants in Marquesas Islands in French Polynesia rarely engage in face-to-face play with their mothers; they most frequently play with the child caregivers (e.g., older siblings). The playful interactions of infants with child caregivers are far more complex, reciprocal, and physically close than those with adult caregivers (see Field et al., 1981).

Differences in Social-Oriented Play

Differing in history, beliefs, customs, and practices, cultures can be broadly classified as with an independent or an interdependent orientation. According to Markus and Kitayama's (1991) conceptualization, cultures differ in their interpretations of self, of others, and of the balance between the two. Interdependent-oriented cultures (e.g., Argentina, Japan, rural India, Kaluli in Papua New Guinea, Nso in Cameroon, and Puerto Rico) are characterized by placing high values on relatedness among individuals and sensitivity to others. In contrast, independent cultures (e.g., France, Germany, and the United States) stress individuals' independence from others, attention to the self, and autonomy in personal choice and action. Differences in the broader cultural models inform socialization goals, guide child-rearing practices, and shape the development of parenting behaviors in specific ways (e.g., Kärtner et al., 2008; Keller et al., 2009, 2010). Whereas caregivers in the interdependent cultures commit to socialization goals such as interpersonal harmony, respect of others, obedience, and obligations, caregivers in the independent cultures place a socialization emphasis on individual achievement, self-affirmation and self-reliance, and assertiveness. Parent–infant social-oriented play reflects the broader socialization goals and is organized in culturally preferred ways. To foster infants' sense of individuality and mastery, mothers in independent cultures often engage in a distal style of playful interactions with their infants by making direct eye contact, orienting infants toward objects and events in the environment, and responding to infant vocal and facial signals with verbalization (Keller et al., 2009; see Bornstein's review in Göncü and Gaskins, 2007). In contrast, mothers in interdependent cultures engage in more person- than object-oriented play with their infants (see Bornstein's review in Göncü and Gaskins, 2007). Consistent with their cultural commitments, mother–infant person-oriented play in these cultures is characterized by a proximal style focusing on body contact and body stimulation (Keller et al., 2009). Compared to American mothers, Japanese mothers have a slower tempo of interactive play, are likely to touch their infants, use upper-body looming to punctuate facial expressions and vocalization, and attract their infants' attention to themselves (see Fogel et al.'s review in MacDonald, 1993). Puerto Rican mothers encourage social dependency, respect, and proper demeanor. Their play with infants is featured by leading turn-taking games requiring close physical proximity, issuing directive commands, focusing and signaling the infant attention on the relationship, and using physical restraint to keep infants oriented toward them (Miller and Harwood, 2002).

Differences in Object-Oriented Play

Although infants across cultures show a universal timing of developmental shift in their interest from person-oriented play to object-oriented play, objects are incorporated into play differently according to specific cultural rule. For East Indian parents, exposure to objects or the physical world is considered as inappropriate for young infants; thus, object stimulation during play is extremely rare (see Roopnarine et al., 1994). !Kung caregivers in northwestern Botswana do not give objects to infants or entertain them with objects. !Kung infants' interest in objects is largely ignored by their caregivers. Echoing the cultural emphasis on interpersonal relatedness, they consistently note infants' vocalizations and smiles occurring during object play (Bakeman et al., 1990). Middle-class caregivers in independent cultures engage in more object- than person-oriented play with infants, follow infant's lead, maintain physical distance, praise infants' play efforts, and issue directives in the form of comments and suggestions. During play, middle-class American mothers emphasize cognitively stimulating didactic actions, prefer to verbally direct infant attention to objects, and use toys as the topic of communication. In contrast, Japanese mothers use toys to mediate person-oriented play with infants (see Bornstein's review in Göncü and Gaskins, 2007; Bornstein et al., 2012). Moreover, although Japanese-American and South-American immigrant mothers living in the United States engaged in more object-oriented play than person-oriented play with infants, both groups of mothers reported that they engaged in more person- than object-oriented play with infants, which is consistent with the larger cultural values of mutual dependence. The paradox in the play behavior and perception in Japanese-American and South-American mothers may indicate that behaviors acculturate (i.e., adapt to a new culture) more readily than beliefs among middle-class immigrant mothers (Cote and Bornstein, 2009).

Differences in Physical Play

Fathers in independent cultures (e.g., Canada, Israel, Sweden, and the United States) engage in more vigorous physical play with their infants than mothers, which has led some researchers to conclude that rough and stimulating physical

play contributes to the development of father–infant attachment. However, physical play between fathers and infants appears to be a cultural-specific phenomenon. Both mothers and fathers in interdependent cultures (e.g., India, Malaysia, and Taiwan) rarely engage in rough and physical play with their infants. Parents in many subsistence cultures (e.g., Akas among the pygmies of Central Africa and Baka in Cameroon) practicing group care also do not engage in rough play with their infants (see Roopnarine's review in Pellegrini, 2011). In Italy, familial and nonfamilial women, but not parents, engage in rough play with infants (see New's review in Roopnarine et al., 1994).

Play during Toddlerhood

During the second and third year of life, toddlers' play becomes more complicated and incorporates imagination and pretense. Across cultures, toddlers engage in a variety of play not only with their parents but also with siblings and peers. Both cultural-general and cultural-specific patterns coexist during this developmental period. Cultural similarities are observed in the developmental emergence of symbolic (i.e., pretense) play and peer play, gender differences in caregiver–toddler symbolic play, and effects of adult play scaffolding. Cultures also differ significantly in adults' support to toddlers' play, caregiver–toddler play preferences, thematic topics of caregiver–toddler play, strategies used to scaffold object play, and toddlers' play partners.

Cultural-General Patterns

Similarities in the Emergence of Symbolic Play and Peer Play

Beginning in the second year of life, children' play becomes distanced from the properties of objects and takes on a nonliteral quality. Anthropological and psychological research indicates that the normative onset of symbolic play is similar across cultures at about 12–15 months. Toddlers begin to engage in symbolic play by reenacting activities by self and others (e.g., drinking from an empty cup). Without adult acknowledgment or support, for example, Mayan toddlers engage in brief episodes of symbolic play using household objects (see Göncü and Gaskins, 2007). Ready imitation of one another between peers during play also emerges at around the same time. Toddlers in Seltaman of Papua New Guinea and the United States are similar in generating a great variety of extended bouts of nonverbal coordinated action by playing reciprocal imitation games (Eckerman and Whitehead, 1999).

Similarities in Gender Differences and Mutual Specificity in Caregiver–Toddler Play

During play, caregivers in both independent (e.g., France and the United States) and interdependent (e.g., Argentina, Italy, and Japan) cultures are similar in their promptness, contingency, and appropriate reactions to toddlers (see Bornstein's review in Göncü and Gaskins, 2007; Suizzo, 2004). Regardless of culture, mothers' praise, affection, and elicitation are unrelated to toddlers' symbolic play. Within the dyadic parent–child play context, mothers in both independent and interdependent cultures engage in more object-oriented play with their boys and more symbolic play with their girls. Similarly, boy toddlers across cultures engage in more object-oriented play, whereas girl toddlers engage in more symbolic play with their mothers. Moreover, a cultural-general pattern of mutual specificity is observed, wherein mothers' frequent exploratory and symbolic play is specifically related to more exploratory and symbolic play in their toddlers, respectively (see Bornstein's review in Göncü and Gaskins, 2007).

Similarities in the Effects of Adult Play Scaffolding

Toddlers across cultures exhibit lower quality of play when playing alone than when playing collaboratively with a mature partner (e.g., mother or older sibling). Scaffolding by a mature play partner enhances the duration, diversity, and sophistication of toddlers' play (see Howes' and Lillard's reviews in Pellegrini, 2011). Regardless of culture, caregivers' redirecting of toddlers' attention away from their current interest similarly decreases play complexity, which may be due to the imposed interruption to the flow of activities. In contrast, caregivers' following of child attention increases play complexity, which may be attributable to the increased opportunity for adult modeling and child imitation of more sophisticated play (Sung and Hsu, 2009). Finally, parents who value play for its educational and cognitive benefits and are knowledgeable about play are likely to encourage toddlers' play, engage in play with their toddlers, and adjust the play level to that of their toddlers (see Bornstein's review in Göncü and Gaskins, 2007; Farver's review in MacDonald, 1993; Haight et al., 1999).

Cultural Variations

Differences in Adult Support

Influenced by cultural values and belief systems, caregivers in different cultures diverge on their views about the centrality of play in toddlers' learning and socialization. The views range from regarding play as an activity with minimal significance that needs to be curtailed to accommodate other responsibilities, such as work (e.g., Gusii and Ngeca in Kenya, Indonesia, and Mexico); to an activity with less significance that is only tolerated without active encouragement (e.g., Guatemala and Italy); to a highly valued activity with adult support and cultivation (e.g., the United States) (see Göncü and Gaskins, 2007). Middle-class American parents perceive play as important for toddlers' development and provide support to their play (see Göncü, 1999; Göncü and Gaskins, 2007). In contrast, mothers of Gusii and Ngeca in Kenya rarely engage in play with their toddlers; instead, they engage in more restricted training interaction to teach their toddlers appropriate social behaviors and work habits (see Field et al., 1981; Göncü and Gaskins, 2007). Because of their role as disciplinarians, mothers may be the least likely playmates for their toddlers in these cultures. Although Italian mothers acknowledge that it is natural for children to play, they do not consider playing with a child is part of maternal role, and only tolerate their children's playful activities (see New's review in Roopnarine et al., 1994). Despite the fact that Mexican and Indonesian toddlers engage in increasingly complex social pretend play, their mothers attribute little importance to play. When asked to play with their toddlers, Mexican mothers engage in

explicitly structured teaching, rather than a child-centered activity (see Farver's review in MacDonald, 1993). Mayan mothers in Guatemala do not recognize play as central to development because they believe that development is generated internally and not influenced by external forces. They discourage children's play, but sometimes tolerate it so that they can be relieved from child care activities and prevent child interference with their work. Less adult support for play is typically observed in cultures where adults have heavy workloads and/or where adult–child interactions generally are more hierarchically organized. American Indian mothers, for example, also facilitate play more often than participate in play (see Field et al., 1981; MacDonald, 1993; Pellegrini, 2011).

Differences in Caregiver–toddler Play Preferences

Even among cultures that value play, significant cultural variations exist. For example, parents in Argentina, France, Japan, and the United States share their views on the importance of play. Yet, because of differences in the history, beliefs, and child-rearing goals, cultural-specific patterns in mother–toddler play have also been documented. Similar to the patterns found in infancy, mothers in independent cultures (e.g., France and the United States) engage in more object-oriented play with their toddlers (e.g., pushing a truck), whereas mothers in interdependent cultures (e.g., Argentina and Japan) engage in more person-oriented and symbolic play, particularly other-directed symbolic play (e.g., feeding a doll) (see Bornstein's review in Göncü and Gaskins, 2007). Compared to Argentine and French mothers, American mothers describe objects and solicit their toddler to engage in symbolic play more often. Presumably, American mothers' preference in encouraging object-oriented play may reflect their emphasis on cultural values related to individual achievement, mastery, and personal choice. In contrast, French mothers tend to remain in a passive and spectator role and prefer an indirect approach of presenting children with options, rather than active stimulation. Argentine and Japanese mothers often solicit and demonstrate symbolic play and praise their toddlers, which are believed to reflect the cultural emphasis on control and interdependency (see Bornstein's review in Göncü and Gaskins, 2007). Mother–toddler play in immigrant families who are adapting to a new culture also demonstrates variations. Mother–toddler play in immigrant Japanese-American and South-American families is more similar to that in American families than to that in their cultures of origin. Immigrant Japanese-American and South-American mothers engage in more exploratory object play and less symbolic play with their toddlers than the dyads in Japan and Argentina (Cote and Bornstein, 2009). Findings with immigrant families support the idea that early play reflects cultural influences.

Differences in Parental Scaffolding of Object Play

Despite the universal benefit of attention-following scaffolding strategy to toddlers' play, mothers across cultures show a distinctive preference for using certain attention regulation strategies and referential speech patterns in guiding their toddlers' play. Mothers in independent cultures (e.g., the United Kingdom, the United States, and Finland) are likely to follow their toddlers' attention and make elaborative comments on their toddlers' actions or the objects involved. On the other hand, Chinese and Korean mothers who are committed to interdependent cultural values are likely to direct their toddlers' attention by introducing a new object or activity and make simple labeling or questions about the object or activity. Mothers' cultural-specific scaffolding strategies appear to echo their divergent cultural concerns and beliefs about early play as a joint activity for promoting individuality and autonomy versus as an educational context for teaching and learning, and for encouraging child compliance, respectively (Sung and Hsu, 2009).

Differences in Play Themes

The thematic topic of toddlers' play is cultural-specific and closely tied to their daily activities. In cultures where toddlers are integrated in adult activities, their play mirrors familiar everyday experiences. Indonesian toddlers, for example, initiate pretend play with their mothers and their pretend play often parallels adult housework activities with family role themes (e.g., Farver and Wimbarti, 1995). The themes of reciprocal imitation games between toddler peers also vary in line with the characteristic play settings. The themes of American toddlers' peer reciprocal games centered largely around play materials (e.g., toys), whereas the themes of peer play for the Seltaman toddlers of Papua New Guinea often resemble adult activities (e.g., beating rhythmically, as in drumming) (Eckerman and Whitehead, 1999).

Differences in Play Partners

In cultures where play is valued, toddlers' primary partners are usually their mothers and other adults. American toddlers play more frequently with their mothers than with their older siblings, and their play with mothers is more complex than with older siblings. In contrast, toddlers in Indonesia, Mexico, and among the Ngeca of Kenya play more with their older siblings than with their mothers. Sibling–toddler play often occurs in the context of sibling caretaking. Older siblings in these cultures provide cognitively challenging and emotionally complex stimulation and make comments and suggestions about play. Toddlers' play behaviors with siblings in these cultures are similar to American toddlers' play behaviors with their mothers. In contrast, mothers in these cultures use more restricted teaching behaviors that involve directing and correcting their toddlers' play (see Farver and Wimbarti, 1995; MacDonald, 1993; Göncü, 1999; Göncü and Gaskins, 2007).

Play during Preschool Age

Children's play reaches its peak at ages 3–5. At this developmental period, play is completely self-initiated without adult support. Even as household work becomes Mayan children's primary daily activity, play remains a dominant place in their activities (20–25% of time) (see Göncü, 1999; Göncü and Gaskins, 2007). Both cultural similarities and variations continuously coexist in preschoolers' play. Whereas gender differences, object use, nonsocial peer play, and the role of child characteristics in play behaviors are similarly observed across cultures, unique differences in ecological conditions,

interpersonal contexts, cultural activities, and socialization goals and practices contribute to cultural variations.

Cultural-General Patterns

Similarities in Object Use, Pretend Play, and Sex Segregation

Regardless of culture, objects are essential to play among preschool-age children. Middle-class children in cultural communities that are more advanced in economic developments typically incorporate manufactured toys (e.g., dolls and cars) into pretend play. In cultural communities where toys are scarce, children constructing props from the materials at hand (e.g., sticks, stones, and kitchen utensils) (Edwards, 2000). Despite marked variations in the frequency and themes of pretend play (see below), children across cultural communities, including those in subsistence societies (e.g., the !Kung San of Kalahari, Marquesan of Polynesia, and Hadza of Tanzania), all engage in pretend play (Edwards, 2000). To create shared understanding and prolong play episodes, children often enact themes that portray familiar adult daily activities (e.g., cooking). The patterns of gender differences in early play vary according to children's age and social contexts (e.g., dyadic parent–child play or peer group play). By age five during solitary and peer play, gender specificity among girls and boys becomes more evident universally. Whereas boys engage more in physical and motor activities, girls engage in more object play and pretend play (Edwards, 2000; Singer et al., 2009). As preschoolers increase their participation in same-sex playgroups, sex segregation becomes more common.

Similarities in Nonsocial Peer Play as Maladaptive

Following a predictable timetable, play progresses from solitary play in the presence of peers toward social play with peers between ages three and five. Play in this developmental period is fundamentally a social activity. Whereas social play with peers is adaptive for children across cultures, nonsocial play is evidenced to be maladaptive. Preschoolers who frequently engage in solitary-passive play (e.g., quiet object explorations and construction activities) and solitary-active play (e.g., repeated sensorimotor actions and solitary pretend play) have similar negative consequences in both independent (e.g., the United States) and interdependent cultures (e.g., China and Malaysia) (Choo et al., 2012; Nelson et al., 2012). Although independent and interdependent cultures diverge on their respective emphases on solidarity and social restraint, nonsocial play in preschoolers is associated with indicators of socioemotional maladjustments such as noncompliance and low prosocial behavior across cultures.

Similarities in the Role of Individual Characteristics

Play behaviors in preschoolers with different cultural backgrounds are similarly associated with the same individual characteristics of the child (e.g., social and cognitive skills). For example, behavioral dispositions including socially adaptive behavioral style, frequent positive social interaction with peers, and high creativity similarly predicted social pretend play behaviors in both Korean- and European-American preschoolers from middle-class families. Such a cultural-general pattern suggests that individual qualities may be just as important for preschoolers' expression of pretend play as culture-specific skills and behaviors (see Howes' and Roopnarine's reviews in Pellegrini, 2011).

Cultural Variations

Differences in Ecological Conditions

Children's play reflects the differences in their ecological environments (Singer et al., 2009). In cultural communities with more advanced economic developments, play is a preferred path to growth and development, which is often viewed as equally important to other goals such as academic success. In contrast, play in subsistence communities is typically utilized as a context to train specific skills for work. Children, particularly girls, as young as age three in many subsistence cultures begin to make a transition from play to work and become an asset to the household economy. In these cultures, as girls take on more work-related responsibilities such as child care and housework and spend less time in play, boys spend relatively more of their time playing (Edwards, 2000; see Göncü and Gaskins, 2007). The availability or constraint of physical space also modifies how children play. Children in subsistence cultures play in open outdoor space. Mayan children, for example, mostly play with objects and engage in gross motor play, but rarely play pretend. When they do, the pretend play tends to be spontaneous and often occurs in large mixed-age playgroups, organized by older children aged 6–11 (see Göncü and Gaskins, 2007). Taiwanese children in an urban city with limited space inside of their homes possess relatively few toys. They are likely to use social routines, not props or toys, to construct joint play with their mothers (Haight et al., 1999).

Differences in Interpersonal Contexts

Children's play depends in part on the availability of various partners (e.g., parents, siblings, peers, and extended family members). With a large number of children available for play, Mayan, Indonesian, Kenyan, and Puerto Rican children often play with siblings and engage in large-group peer play (Edwards, 2000; Trawick-Smith, 2010). A comparative study (Haight et al., 1999) showed that Irish-American preschoolers played pretend more frequently with other children due to their close social networks, whereas Taiwanese preschoolers pretended more with their caregivers due to their limited access to peers. In addition, as discussed above, adults' attitudes toward the significance of early play influence their beliefs about the appropriateness of participation in children's play. Consistent with their beliefs about the benefits of play for children's development and the greater informality in the relationships between children and adults, European-American parents and teachers emphasize play over academic tasks and frequently participate in children's play (see Roopnarine's review Pellegrini, 2011). On the other hand, Asian (e.g., East Indian, Chinese, Korean, Pakistani, and Thai) and Asian-American parents and teachers rarely play with children, viewing play as a culturally inappropriate adult behavior and an activity with little educational values (see Roopnarine's review in

Pellegrini, 2011). Caregivers in many subsistence cultures believe that children learn through work and not play, so they neither encourage children to play nor see themselves as adequate playmates for children (see Pellegrini, 2011; Singer et al., 2009). Caregivers in cultures where play is valued capitalize on children's interest in play and use it as an opportunity for socializing their preschoolers' culturally appropriate behaviors. For example, influenced by Confucian principles, mother–child play in Taiwanese families is characterized as didactic, with more mother-initiated interaction and a thematic highlight on proper conduct. Following a child-centered approach to socialization, European-American mothers allow their children to initiate and lead pretend play; their play is featured by mutuality and a thematic focus on child fantasies (Haight et al., 1999). Acculturation and assimilation of a new culture can modify immigrant parents' beliefs about play and play participation. Middle-class Korean-American mothers with greater cultural integration are more accepting and encouraging of preschoolers' play and report more parent–child play than those with less cultural integration. Korean-American children whose mothers are culturally assimilated and acculturated also participate in more pretend play (see Pellegrini, 2011).

Differences in Cultural Goals and Practices

Play is a form of personal expression by which children express their feelings and real-life experiences. Play also represents children's close observation of the common practices of their culture and attempts to make sense of their cultural experiences. During play, children often enact themes that are important to a particular culture, through which they practice cultural routines and customs. The themes of Mayan children's pretend play, such as playing house or selling produce, mirror adult life (see Gaskins' review in Göncü, 1999). Reflecting the collective orientation and oral storytelling traditions, music play is common among Caribbean preschool-aged children. Puerto Rican 4- and 5-year-olds often share songs, collaborate on the creation of dances, and pretend to be musical performers or dancers (Trawick-Smith, 2010). Thematic contents in peer play appear to resonate with differences in cultural orientations. Middle-class Korean-American children use greater formality and an honorific speech format to enact pretend roles with high status (see Pellegrini, 2011). Consistent with the cultural expectations for self-reliance, independent thinking, and creativity, European-American children engage in pretend play with fantasy themes more than Korean-American children (see Farver et al., 2000). As a reflection of Korean culture's emphasis on group harmony and cooperation, Korean-American children's play focuses on realistic everyday activity and familiar family role themes that can be easily shared. Communicative strategies used by children to structure and maintain pretend play are also consistent with the larger cultural rules. During dyadic peer play, European-American children are more self-assertive and disagreeable, as they describe their own actions, reject their partners' suggestions, and use directive commands. In contrast, Korean-American children are more agreeable and cooperative, as they describe their partners' actions and use polite requests and agreement statements (see Farver et al., 2000; Roopnarine's review in Pellegrini, 2011).

Conclusion

Children bring culture into play. Early play functions to express children's personal experiences of growing up in a cultural setting and to socialize them into accepting and practicing cultural customs for appropriate behaviors. Play may further shape children's cultural experience and bind them to their culture. As a dynamic co-construction between children and their culture, there are many cultural models of play that represent children's experiences in their ecological, interpersonal, and developmental contexts.

Early play by children and their play partners has both, invariant cultural-general and variable cultural-specific dimensions that result from the dynamic interplay between biology and cultural experience. Early play not only has neurobiological underpinnings within the child, but also is influenced externally by caregivers' culturally appropriate behaviors that may inhibit or promote early play. As a culturally mediated activity, play in infancy and early childhood varies in development, varieties, structures, and functions. Cultural variations in early play are not signs of deficiency or neglect (Lancy, 2007; Roopnarine et al., 1994). Rather, cultural differences are reflections of variations in economic and physical ecology (e.g., rural fishing village, urban suburb, or neighborhood), physical context (e.g., availability of space), arrangement of interpersonal context (e.g., availability of play partners), cultural scripts for everyday activities and social conventions (e.g., autonomy or relatedness emphasis), and adult beliefs and expectations for play (e.g., enhances necessary skills or hinders productive activity) (Haight et al., 1999).

Furthermore, a great range of differences within a culture (i.e., within-cultural variations) that change with the characteristics of the child (e.g., age and sex), the parent (e.g., education and acculturation), the family (e.g., socioeconomic status), and the neighborhood are also expected (see Cabrera et al., 2006; Farver et al., 2000; Kenney, 2012; MacDonald, 1993; Roopnarine et al., 1994; Pellegrini, 2011). A culture-sensitive theory of play should seek to understand how both between- and within-cultural variations contribute to the development of early play over time. Accounting for between- and within-cultural variations will require attention to a multitude of biological, developmental, social, and cultural factors. A longitudinal, multilevel, and multicultural approach to the dynamic, complex process of interplays among characteristics of the child, the play partner (e.g., parents and siblings), and the family will be necessary.

Plea Bargaining: A Comparative Analysis

This article is a replacement of the previous edition article by M. Heumann, volume 17, pp. 11507–11513, © 2001, Elsevier Ltd.

Abstract

Plea bargaining is a well-established phenomenon in the United States, such that it is regarded even by the Supreme Court as part of ordinary criminal justice practice, to which Constitutional rights should attach. Various forms of plea and sentence negotiation procedures also exist across Europe and the desire to minimize the number of fully contested trials appears to be a universal criminal justice objective. This article explores the types of bargaining in place in a range of jurisdictions. It focuses in particular on the implications of party-controlled negotiations within more inquisitorial procedures, which are generally characterized by a proactive and truth-seeking judicial function.

Introduction

Plea and sentence bargaining is characterized by several general features that we might recognize as common across a range of jurisdictions and procedural traditions. It requires an admission of guilt from the accused; the accused is offered some reward, incentive, or advantage, either in exchange for, or as a result of the plea; and there is some benefit to the criminal justice system – typically the avoidance of a more lengthy and expensive contested trial. The point in the criminal process at which these negotiations are initiated, the personnel involved, and the relative incentives and benefits available will of course differ. In some instances, explicit bargains are struck between prosecutor and defense lawyer; in others, there is direct judicial involvement; and in others, the system benefit may operate as an implicit reward, without any explicit bargaining taking place.

Growing criminalization coupled with the need to reduce the cost and delay brought about by increasing caseloads makes such bargaining an attractive option. The phenomenon of 'negotiated justice' is well established and has saturated the US criminal system, but we now see various forms of bargaining across the globe. In Europe, for example, in 1987, Recommendation R (87) 18 of the Council of Europe Committee of Ministers encouraged countries to make use of discretionary prosecution and the adoption of summary, simplified and out-of-court procedures for mass and minor offenses, in order to combat delay and to simplify the workings of criminal justice. Formal procedures have been introduced in many jurisdictions (e.g., the *conformidad* in Spain; the *confissão* in Portugal; the *composition pénale* and the *comparution sur reconnaissance préalable de culpabilité* in France), and informal procedures (such as the German *absprachen*) have been placed on a statutory footing. Bargaining exists even in international criminal justice, though the implications are rather different from those in domestic procedure (Langer, 2004, 2006). In both the domestic and the international sphere, the court's verdict represents an official truth or history of the case, a formal finding as to guilt. In the international criminal justice arena, negotiating what will be an important historical record of events has wider implications for reconciliation and justice for victims.

These procedures are not about acknowledging the remorse of the accused, or, arguably, even her guilt, so much as maximizing the efficiency of case management procedures. They are less widespread in continental European jurisdictions (they account for around one third of all cases dealt with by the courts in Italy, for example) but in England and Wales and the United States, guilty pleas have become the norm, even the expectation. Some 70% of cases before the courts are dealt with by way of guilty pleas in the Crown Court in England and Wales, and 68% in the magistrates' court (75% excluding cases that are discontinued at court). In the United States, around 95% of cases in both state and federal district courts are disposed of by way of guilty pleas (**Figure 1**), causing one commentator to observe: "This system loves punishment … This system hates trials" (Miller, 2004: p. 1212). Criminal justice systems are simply not equipped for a mass of contested trials. The full hearing of a case with live witnesses, in which the prosecution case is tested and rules of evidence applied, exists more as a promise or guarantee. It is the possibility of the trial that shapes the nature of the parties' pretrial behavior to some degree.

Understanding Plea Bargaining Comparatively

In Anglo-American systems of criminal justice, the parties are responsible for the investigation, collection, and presentation of evidence; the trial judge or the jury will then assess this evidence, whether written reports or live testimony, in order to determine the verdict. As untested evidence is brought directly by the parties, often complex rules of evidence determine admissibility. With the parties in control of the case in this way, prosecutors are at liberty to negotiate the evidence and the charges. For at least four decades, American scholars have marveled at the relative absence of plea bargaining in most continental European countries whose procedures are rooted in the inquisitorial tradition.

Europe is no longer a 'land without plea bargaining' (as Langbein referred to Germany in 1979), but while some form of plea or sentence bargaining probably now exists in most European countries, the nature and extent of the practice is still very limited compared with the routinized nature of negotiated justice in the United States and increasingly in England and Wales. (For an account of trial avoidance in various jurisdictions,

Figure 1 (a) Number of pleas vs trials in Federal Courts (federal data); (b) Number of pleas vs trials in 75 Major County Courts (state data). Source: Online Sourcebook of Criminal Justice Statistics, located at http://www.albany.edu/sourcebook/.

see Thaman, 2010.) In particular, the scope of plea bargaining is very different: plea bargaining is used across the full range of offenses in Britain and the United States, but in most inquisitorially rooted procedures, it is limited to less serious cases. Germany is perhaps the exception to this, where sentence bargaining practices have developed informally (they were not regulated by statute until 2009) and so they were free from the constraints of procedural principles and are applied to both serious and minor offenses (Weigend, 2008; Rauxloh, 2011).

In inquisitorially rooted systems such as France, Spain, or the Netherlands, the judge has a strong fact-finding and truth-seeking role, which is more investigative in nature than the passive and purely adjudicatory function of the judge within the adversarial tradition (e.g., in the United States). Inquisitorial procedures will typically include a pretrial judicial (or at least prosecutorial) function, in which a judicial officer is responsible for conducting or overseeing the investigation. This affects the relationship between trial and pretrial behavior as the prosecution case is considered the product of a judicial (or judicially supervised) investigation, rather than a partisan account to be tested by the defense. The trial of course yields the public pronouncement of the verdict, but rather than being the first hearing and testing of the evidence, it is the confirmation of an earlier set of data-collecting moments. As a result, the trial in more inquisitorial procedures is typically shorter, with fewer witnesses, and so is less resource intensive – it is a trial on the dossier (the case file of evidence), predictably often confirming the assertions of the 'judicial' prosecutor.

It might be presumed, therefore, that in inquisitorial-type systems there is less pressure toward a guilty plea given the more perfunctory trial process than exists in adversarial systems, which have a greater incentive to avoid the lengthy and complex process of the contested trial. Yet, even without a formal system of pleas, it is clear that in France, a confession is the primary goal of the police investigation despite it being carried out under the apparent supervision of the public prosecutor (Hodgson, 2001). Interestingly, some older studies in the United States have also doubted the extent to which caseload pressure is the real reason for trial avoidance (Mather, 1979; Schulhofer, 1984). But while the certainty of a confession is perhaps universally desired by those responsible for the investigation and prosecution of crime, greater opportunities to contest the evidence bring yet more pressure to close down the uncertainty of conflict. It would seem that the introduction of improved procedural defense rights immediately triggers the establishment of procedures through which these rights can be waived. In the 1990s, for example, when Italy was moving to a more accusatorial procedure in which written evidence was replaced by oral evidence at trial, realizing the huge time and resource implications, the reform retained a simplified 'trial by dossier' procedure (see generally, Pizzi and Montagna, 2004; Illuminati, 2005). It recognized that the adversarial ideal of the fully contested trial following a plea of not guilty would not be sustainable in all or even most cases.

Objections to Plea and Sentence Bargaining

At one level, encouraging the guilty accused to admit her guilt sooner rather than later seems quite logical. Yet, even in theoretical terms, the plea and sentence bargaining process might subvert criminal justice norms in several ways.

Supplanting the Role of the Court

Firstly, the court is no longer the arbiter of fact and judges no longer enjoy primary responsibility for case disposition. Instead, the court agrees to an outcome determined by the parties. This objection might be raised more generally against any system of guilty pleas, but it is especially problematic when incentives and rewards are offered. The shift in power from the judge to the parties poses particular problems in jurisdictions rooted in inquisitorial procedure, where the court, rather than the parties, has the primary responsibility for fact-finding.

For example, until relatively recently, France made no formal distinction between cases where the accused admitted the offense and those where she did not: cases were simply dealt with more or less rapidly depending on whether there was an admission (Hodgson, 2012). In 2004, a form of guilty plea procedure was introduced, underpinned by a process of sentence bargaining – the *comparution sur reconnaissance préalable de culpabilité* (CRPC). Where the accused has admitted the charges, the prosecutor can propose a reduced sentence of up to 1 year or half of the maximum sentence for the charge. If the defense agrees, the accused will have her case dealt with by the rapid guilty plea process. The court may only agree or reject the sentence – she may not adjust it in any way. It has been argued that this undermines the proper function of the judge and so the separation of powers. However, the Constitutional Council has ruled the procedure to be constitutional: the judge must do more than rubber stamp the agreement and may reject the plea and sentence if not supported by the facts, or after taking into account the

personality of the accused, the situation of the victim, or the public interest. (The same is true in Italy – the judge may only accept or reject the sentence proposed, but she is required to satisfy herself of the voluntariness of the admission and the evidence against the accused, thus retaining something of the traditional truth-finding judicial role.) In practice, the procedure is designed for a speedy resolution and it seems unlikely that the judge would go beyond the agreement presented to the court. The procedure has been extended to virtually all middle-ranking offenses (*délits*), and while it is currently applied immediately after the police detention and questioning of the suspect, it may now also take place at the close of the judicial investigation (*instruction*). Its use has increased each year and now accounts for 15% of all cases dealt with by the *tribunal correctionnel*.

The Invisible Exercise of Discretion

Second, in the process of plea and sentence bargaining, in most instances (Germany is an interesting exception here, where the defense lawyer negotiates directly with the judge), prosecutorial discretion is supreme and is largely invisible to scrutiny. These are deals behind closed doors, with no record of terms or reasons. In the United States, as power has shifted to the prosecutor, she has been given greater power to charge offenses and so greater bargaining power over charge, plea, and effectively sentence. Miller and Eisenstein (2005) found that increased cooperation between state and federal prosecutors, especially post 9/11, has moved sentencing power away from the judge to the prosecutor in federal cases. Miller (2004) argues that increased federal sentencing mandatory provisions, together with an increase in the range of crimes that are the focus of federal attention, have increased the power of the prosecutor. As a result, there are almost no trials taking place in federal court (the percentage of convictions resulting from guilty pleas having risen from 87 to 97% between 1991 and 2003), with the result that the federal prosecutor has become the federal sentencer. Mandatory sentences have also increased prosecutorial power in the same way, as the choice of charge will effectively determine sentence. In England and Wales, a recent development seeks to regulate the prosecutor's exercise of discretion in plea bargaining in serious fraud cases, ensuring greater fairness, avoiding improper pressure and keeping records of discussions. However, the disclosure provisions remain largely within the prosecutor's discretion, potentially undermining fairness (see Section Inequalities of Bargaining Power: Legal Assistance and Disclosure). Nonetheless, Watson (2010) argues that the guidelines may have a positive impact on the plea bargaining culture, creating a more formal and transparent system.

In jurisdictions where the prosecutor is a judicial officer, there is greater trust in the apparently nonpartisan nature of the prosecutor and the accused may appear to be more protected. For example, in France, the *procureur* is a *magistrat* along with the *juge d'instruction* and the trial judge. She is understood to act in the public interest, in contrast to the defense lawyer, who represents the accused in a more partisan way. However, research shows that in practice, the prosecution function is less judicial and public interest-centered and more partisan and prosecution-oriented than might be assumed (Hodgson, 2001, 2005). As a prosecuting party with hierarchical accountability to the executive, the European Court of Human Rights has also questioned the independence and so the judicial status of the French prosecutor in particular, though this applies potentially to many other jurisdictions whose prosecutors share her role and status (*Medvedyev v. France* 2010, 3394/03; *Moulin v. France* 2010, 37 104/06).

The public interest orientation of the continental public prosecutor should not be overplayed, but she does nevertheless play a different role from her British and American counterparts. While plea bargains in England and Wales and the United States might be struck between the prosecution and defense lawyers before being put to the accused by her own defense counsel for a plea of guilty to be entered, the French prosecutor's responsibility for the investigation makes her a more proactive prosecutor, engaging directly with the accused. She will first propose a sentence and then during a short hearing with the accused and her lawyer, the accused will be asked to confirm that the offense is admitted. If it is not, the prosecutor will simply remit it for ordinary trial. If it is, the prosecutor will listen to the defense mitigation, before proposing a revised, lesser sentence.

The power of the prosecutor as sentence negotiator is strongest where the prosecution function includes making a sentence recommendation to the court (such as in France) and so can control the entire case outcome. The prosecutor's discretion, and so her power as a negotiator, is weaker where there exists a judicially structured sentence discount, often framed either through guidelines or a fixed mandatory discount (though ironically this may increase her power in charge selection). In Spain, for example, defendants receive a mandatory one third sentence discount: there is an incentive, but the incentive itself is not negotiable. In these cases, the charges remain fixed and it is only the sentence that alters. More than 60% of cases in Spain are now dealt with through this procedure. In England and Wales, the prosecutor makes no sentence recommendation, but the judge may give an indication of sentence following a guilty plea (*Goodyear* [2005] EWCA Crim 888) and legislation provides for a sentence discount of up to one third. This is not mandatory in all cases as with Spain, but rather, the discount is greater the earlier the accused makes an admission. The court is required to state the sentence reduction applied and there are sentencing guidelines to structure this and provide a degree of consistency. In Italy too, where the parties agree the sentence (there is no charge bargaining), a discount of up to one third is available.

In sentence bargaining, such as that in France, there must be a clear admission to the offense being prosecuted. In England and Wales, an admission is not a precondition to the bargaining process, as it is the charge itself that will be negotiated. What is needed is a willingness to admit to something. This is built into the process; when advising the police on what to charge, Crown Prosecutors will note on the file from the outset the charges to which they are prepared to accept a plea of guilty. This, of course, runs the risk of even unconscious overcharging in order to build in space for later negotiations.

Inequalities of Bargaining Power: Legal Assistance and Disclosure

Third, equality of bargaining power is essential if the plea or sentence bargain is to be regarded as fair in any sense. There is

an assumption that bargaining takes place in the shadow of the trial and the promise it represents, without acknowledging the inequalities in bargaining power and the risk of a higher penalty if the right to trial is in fact exercised. There are two particular difficulties in ensuring that the accused is an equal negotiator in this process: she requires effective representation and full disclosure of the prosecution evidence.

The pressures of bureaucratic case management and the financial disincentives to take cases to trial make effective legal representation problematic even in adversarial-type procedures, and researchers have been critical of defense counsel's role in pressing accused persons to accept a plea deal (McConville et al., 1994). This is significant, as the courts assume defense counsel is a kind of guarantor of the voluntariness of the defendant's plea. For example, France ensured the right of the accused person to consult with a lawyer during the CRPC procedure.

Yet, despite their reliance on lawyers in this way, historically the judiciary has ignored the realities of plea bargaining and engaged in what Bibas (2011: p. 1119) describes as "anachronistic formalism focused on jury trials." The courts in England and Wales are also extremely reluctant to look behind a guilty plea and in particular to criticize legal advice on plea. In the United States, Bibas (2011) argues that *Padilla v. Kentucky* 130 S. Ct. 1473 (2010), in which the Supreme Court held that defective advice as to the collateral consequences of a guilty plea (here, deportation) could violate the defendant's Sixth Amendment guarantee of effective legal assistance, signals a shift toward acknowledging guilty pleas as the norm. Furthermore, it recognizes that 'plea bargaining needs tailored regulation in its own right, not simply a series of waivers of trial rights' (Bibas, 2011: p. 1138). The subsequent cases of *Lafler v. Cooper* 132 S. Ct. 1376 (2012) and *Missouri v. Frye* 132 S. Ct. 1399 (2012) have set this out more explicitly: the accused was prejudiced by counsel's failures during the plea bargaining process and the court ordered new trials. Justice Kennedy, writing for the majority, stated that plea bargaining is the norm of the criminal justice system, therefore 6th Amendment guarantees must apply there too, as well as during trials. Alschuler (2013) is skeptical of the significance of these two decisions, arguing that they will neither remove the temptation for lawyers to disregard their client's best interests, nor ensure effective legal assistance. Plea bargaining remains private and cases such as these two rely on defense counsel being forthcoming about their own unprofessional behavior.

The problem of legal assistance is more acute in many inquisitorially rooted procedures, where there is a less established defense role given the historic reliance on, and trust of, judicial investigations. In France, the defense had almost no role in the pretrial investigation until recently, and even now it is severely limited: the suspect may have a 30 min consultation with her lawyer and the lawyer may be present during the police interrogation but may not intervene or ask any questions until the questioning has finished. The lawyer is told only the basic reasons for arrest and detention. Placing the lawyer in a direct dialogue with the prosecutor during the CRPC procedure was therefore a new development and nearly a decade on, the procedure seems to work effectively. The prosecutor proposes the sentence, the defense lawyer points out weaknesses in the case and mitigates for the accused, usually resulting in the prosecutor further reducing the sentence offer.

If there is to be equality of bargaining and if guilty pleas are to be fair and not simply a way of enabling poor investigations to go unchecked, the accused needs to know the nature of the evidence against her. In all jurisdictions, disclosure at or before the first hearing will typically be a summary of the evidence together with the written statements of the key witnesses, though the stage and the extent of disclosure differ. For example, in France and the Netherlands, lawyers are relative newcomers to the police station environment and are told very little about the accusation during the detention and interrogation of the suspect. Lawyers in England and Wales have been present at this stage in the process for nearly 30 years. Relationships of trust have been built and the defense role has become more accepted. Lawyers are therefore told much more of the evidence against the suspect, allowing the defense to begin to structure the defense case at this early stage, including the offenses to which the accused should and should not plead guilty. In sentence bargaining such as the plea system in France, the essence of the bargain is that the accused accepts the facts as presented: this is a necessary precondition to the abbreviated procedure. In plea bargaining cases, however, such as in the United States and England and Wales, the prosecutor may also engage in fact bargaining, agreeing to adjust the agreed facts, by, for example, putting in evidence to the court that the victim was slapped but not punched. This bargaining requires a degree of trust between defense and prosecution, as there is no opportunity to test out the evidence gathered by the police. It is not clear that this trust is well-founded. The prosecutor has no involvement in the investigation and will often have no more idea of the nature or reliability of the evidence than the defense. This is true even in systems where the prosecutor is responsible for the investigation (such as France and the Netherlands) as supervision is, at best, by telephone and file review (Hodgson, 2001, 2005).

Disposing of Cases Earlier in the Criminal Process

Plea and sentence bargaining sit within a wider trend toward the earlier and more rapid disposition of cases. From abbreviated trials to penalties administered by prosecutors and even police officers, legal systems have developed an array of measures that limit the number of cases coming before the court. (See, for example, the French *composition pénale*, in which the prosecutor proposes measures similar to court penalties; the Italian *patteggiamento*, in which the accused agrees a penalty reduction with the prosecutor, reviewed by the judge and *giudizio abbreviato* or abbreviated trial where the penalty is reduced in exchange for an abbreviated trial on the dossier; and the German *strafprozessordnung*, which enables prosecution to be avoided in exchange for the defendant paying money to the victim, a charity, or the state.) As guilty pleas and alternatives to prosecution become the norm, the focus shifts not just to obtaining an admission, but rather to obtaining an admission as early as possible in the process. In England and Wales, out-of-court disposals peaked in 2007 when they outnumbered those cases disposed of at court, though they

have slowly declined since then (see Hodgson and Roberts, 2010). The inequalities of defense representation and evidence disclosure are greater the earlier in the process that the deal is struck.

Prosecution discretion is also stronger when bargaining takes place as an alternative to prosecution. The Netherlands, for example, has a target of disposing of 80% of cases at the police investigation stage, avoiding prosecution. This is tolerated in inquisitorially rooted procedures, because of the trust in the apparent public-interest orientation of the public prosecutor. However, even where the prosecutor is responsible for the investigation in countries such as France and the Netherlands, they will know little of the detail and strength of the evidence: it is unlikely that the police interrogation of the suspect will have been heard, or closed circuit television (CCTV) evidence viewed. Disposing of cases ever earlier in the process means that both defense and prosecution case knowledge is incomplete and the inequalities of bargaining power are therefore weaker.

Where suspects receive deal offers while in police custody or at the first court appearance, in many jurisdictions they will most likely be represented by a duty lawyer who has little or no knowledge of the accused or her case, placing them in a poor position to negotiate. Recent research on the organization and delivery of custodial legal advice shows that arrangements vary across jurisdictions (Blackstock et al., 2014). In England and Wales, custodial legal advice has been in place on a statutory footing since 1984 and is supported by a publically funded legal aid scheme. Duty lawyers are available but suspects may also select their own lawyer, and in most instances, the same lawyer (or at least the same firm) will go on to represent them at court.

This is very different from France and the Netherlands, where most suspects will be seen by one duty lawyer at the police station and a different attorney in court. In this way, legal assistance during police detention and interrogation is a discrete transaction, rather than part of a continuous engagement with the defense case. This has important consequences for the defense's ability to assess the strength of the prosecution case. For example, the prosecution will typically disclose a summary of the suspect's interrogation by the police. If the lawyer in court was not present at this interrogation, she cannot independently judge the accuracy of this summary – which is of concern, because the summary is prepared by police staff and tends to reflect the police interpretation of events, minimizing mitigation or exculpatory comments. In France, the defense may only view the video recording of the interrogation (used in juvenile cases) if the summary is disputed. But as the lawyer at court is unlikely to be the same attorney present during the interrogation, she will have no personal knowledge of the case beyond what the accused is able to tell her.

The quality of legal representation is also variable. In countries where custodial legal advice has recently been introduced or strengthened (largely as a result of the European Court of Human Rights case *Salduz v. Turkey*, 2008), duty rotas are staffed by lawyers with little or no criminal law experience in order to spread the workload – and in some instances to enable lawyers to build up a criminal practice. This replicates in part what happened in England and Wales in the early years following the introduction of the statutory right to custodial legal assistance: lawyers could not accommodate the additional workload and relied on inexperienced and unqualified staff (McConville and Hodgson, 1993). Suspects are the losers in this – the courts deal with them as though they have received effective legal assistance, when in fact they have not. As a result, accused persons are prevented from challenging evidence in court, as the presence of a defense lawyer is deemed to be adequate protection and a guarantee of procedural fairness.

Is Plea Bargaining Typical of Adversarial Procedure?

Plea bargaining is more predominant in adversarial procedures and scholars in both the United States and Britain have argued that it subverts the adversarial process: it removes cases from trial and so prevents the defendant from testing out the prosecution case. If the prosecution is not required to discharge the burden of proof in a public courtroom, this leaves space for weak cases to go unchecked and the adversarial ideal is undercut. Research suggests that this is precisely what does happen. Prosecutors file weak cases, in the knowledge that the vast majority will result in a guilty plea. Incentives and inducements can only accentuate this.

On the other hand, where plea and sentence bargaining has been introduced elsewhere, it is regarded as a more adversarial practice that undercuts and even subverts inquisitorial ideals and procedures. The essence of plea and sentence bargaining is that it is party centered – the plea and sometimes sentence is determined by the prosecution and defense, not by the court. As inquisitorially rooted procedures traditionally have a more active judicial role at trial – questioning witnesses and interrogating the evidence – passing the finding of guilt and the sentence to be imposed into the hands of the parties can be seen as deviating from the inquisitorial tradition and the truth-finding role of the judge. This was the problem raised in the introduction of the French guilty plea procedure. In Italy too, initial attempts at the introduction of an adversarial procedure in 1988 were resisted strongly by the judiciary and required constitutional change. Legal cultures are slower to adapt, and the idea of negotiated justice with contractual-type relationships does not sit well with the traditional public-interest-oriented Italian judicial role (Maffei, 2004).

Whatever the procedure within which bargaining takes place, it requires the accused to waive her trial rights and so the opportunity to test out the accusation against her. What does she receive in return? Is it a bargain, a lesser punishment than she deserves, as Justice Scalia claimed in *Lafler*? This certainly seems unlikely in the United States, where the "expected post-trial sentence is … like the sticker price for cars: only an ignorant, ill-advised consumer would view the full price as the norm and anything less a bargain" (Justice Kennedy in *Lafler*, quoting Bibas, 2011: p. 1138). In inquisitorial-type systems, bargaining is less widespread and not yet institutionalized to the extent of systematic overcharging. The more active judicial and prosecutorial functions also appear to guard against the worst excesses of purely negotiated justice, for the time being at least.

Pluralism

Richard J Ellis, Willamette University, Salem, OR, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The term 'pluralism' was first introduced into political science by the Englishman Harold Laski who used it to designate an early twentieth-century school of political and legal thought that sought to vindicate the rights and autonomy of associations by challenging the modern doctrine of unlimited, unitary state sovereignty. In the second half of the twentieth century the term became associated with a diverse group of American political scientists who traced their intellectual roots to Arthur Bentley and to the empirical study of pressure groups in the 1920s and 1930s. The emphasis in this postwar pluralism was less on the normative desirability of groups than on the empirical power of groups as an explanatory factor in political and social life. A term of many meanings, empirical as well as normative, pluralism has been a target of many criticisms, some of which are warranted, many of which are not. Ironically, while criticisms of pluralism as an empirical theory have intensified over the last decades of the twentieth century, the appeal of pluralism as a normative vision has undergone a marked revival in recent years.

The concept of 'pluralism' is usually associated with post-World War II American behavioral political science, but pluralism's roots extend back to the early twentieth century, and are as much European as American. The Englishman Harold Laski introduced the term 'pluralism' into political science in a number of essays published mostly while teaching at Harvard University between 1916 and 1920. For the term, Laski was indebted to the pragmatist philosophy of William James, whose book, *A Pluralistic Universe* (1909), Laski hailed as of "vital significance for political theory." In philosophy, pluralism, as distinguished from 'monism,' denoted a system of thought which recognizes more than one ultimate principle. Although Laski borrowed the word 'pluralism' from American pragmatism, the ideas he advanced under the rubric of pluralism were taken largely from a heterogeneous group of European, and in particular English, legal historians and political theorists whose work Laski encountered while a student at Oxford immediately prior to World War I. Among the most important of these were the German medievalist Otto Von Gierke; England's preeminent legal historian, Frederick Maitland; J. Neville Figgis; and Laski's Oxford tutor, Ernest Barker, who in 1914 coined the terms 'polyarchism' and 'the new federalism' to describe this new set of ideas.

The English pluralists (as they would come to be known by the time Laski returned to England in 1920) sought to vindicate the rights and autonomy of associations by challenging the modern doctrine of an unlimited and unitary state sovereignty. Pluralists drew an invidious contrast between the 'federalistic structure of medieval society,' in which a dense network of autonomous associations flourished, and the modern notion of state sovereignty that reduced "to impotence and then to nullity all that intervenes between Man and State" (Nicholls, 1975, p. 162). But pluralism was much more than a lament about the world that had been lost; it was also an empirical critique of the concept of sovereignty. Sovereignty was a myth, the English pluralists maintained. The world, Figgis explained, is "not, as a fact, composed of a few vast unities known as States, set over against crowds of isolated individuals." Rather each society "is a society of societies, each and all with rights, liberty and life of their own" (Nicholls, 1975, p. 140). The idea of unlimited state sovereignty, Laski agreed, was "out of accord with the facts of life" (1921, p. 236); the "history of societies" showed that organized groups, even unpopular ones like militant female suffragists, striking miners, or conscientious objectors, imposed limits on the allegedly sovereign state, forcing public officials to adopt policies to which they were opposed (1917, p. 12).

Although pluralists frequently appealed to "the real facts of human society" (Nicholls, 1975, p. 141), their challenge to what they termed 'the monistic theory of the state' was more normative than empirical, though typically the 'is' and the 'ought' were woven seamlessly together. In arguing that "the state is only one among many forms of human association" (Laski, 1919, p. 65), for instance, Laski meant not only to highlight the empirical fact of the social and political importance of associations and groups, but also, and more importantly, to advance a radically anti-statist normative vision. For the young Laski, the state was owed no more loyalty than other groups; each group, including the state, deserved only the loyalty it earned "by virtue of its achievement" (1921, p. 170). The 'ought,' in Laski's mind, derived from the 'is'; it was the "facts themselves" that "dissolve … the inherent claim of the State to obedience" (1917, p. 23).

Not all pluralists shared Laski's anarchic and syndicalist sympathies. Others, such as Figgis and Barker, allowed that the state had an important role to play in regulating conflict between associations and thus in creating the political conditions necessary for associations to pursue their own ends. Although Figgis and Laski disagreed on what should replace the monistic state, they both looked to pluralism less to explain the world than to change it. Their main objective was to help the groups they cared most deeply about, which, in the case of Figgis, an Anglican priest, were religious associations, and in the case of Laski as well as the guild socialist theoretician, G.D.H. Cole, were labor and the trade unions. And herein lies an explanation for English pluralism's precipitous decline in the 1920s. For pluralists failed to persuade others, or even eventually themselves, that pluralism was the most effective means to aid the groups they wanted to assist. Laski himself gradually abandoned or watered down his pluralist ideas

 http://dx.doi.org/10.1016/B978-0-08-097086-8.93092-7

because, along with the rest of the left, he came to believe, particularly after the Great Crash of 1929, that labor had more to gain from an active, even paternal, state than from a minimal, pluralist state.

Ironically, at the same time that English pluralism as a normative vision and intellectual force was in decline, the empirical study of organized groups was gaining ground in American political science, particularly after the publication of Peter Odegard's *Pressure Politics: The Story of the Anti-Saloon League* (1928) and Pendleton Herring's *Group Representation Before Congress* (1929). These sorts of empirical studies of the role of organized groups in the American political process never interested Laski. Indeed, they only confirmed his belief that the trouble with American political science was that "everywhere the emphasis is on description and not principle" (Runciman, 1997, p. 192), a diagnosis diametrically opposed to that held by most American political scientists interested in the role of groups during this era. They believed, with Arthur Bentley, that there was too much moralizing about the evils of special interest groups and too little objective empirical description and analysis of group behavior in the political process. Over the next quarter century American political scientists worked diligently to remedy these empirical shortcomings, such that by 1950, a year before the publication of David Truman's landmark book, *The Governmental Process*, Merle Fainsod could conclude that "there are few fields which American political scientists have cultivated as intensively and profitably as the analysis of the dynamic interplay of interest groups as they give shape to public policy at almost all governmental levels" (Crick, 1959, p. 118).

In 1950 the discipline was relatively rich in empirical studies of interest group influence but the term 'pluralism' was rarely if ever used, though political scientists were beginning to speak of the "group basis of politics" (Latham, 1952) or the "group theory of politics." Truman as well as Bertram Gross had helped to revive interest in Bentley who, in his 1908 book, *The Process of Government*, had argued that groups, not laws, institutions, or constitutions, were the essential "raw materials" of government. Truman followed Bentley in trying to understand the government process by treating groups, specifically interest groups, as "a primary unit of analysis" (Truman, 1971/1951, p. xix). Over the next decade, this increasingly influential mode of analysis would become known by advocates and even more frequently by detractors as 'analytical pluralism' or simply 'pluralism.'

Critics were quick to charge pluralists with believing that groups were all that mattered, often pointing to Bentley's audacious remark that "when the groups are adequately stated, everything is stated" (1967/1908, p. 209). But most of those tagged as pluralists, including most especially Truman, never maintained anything so implausible. Pluralists looked to groups as "*a* major explanatory variable" (Truman, 1971/1951, p. xxii; emphasis added), but explicitly rejected the notion that government officials merely passively registered or mirrored the sum total of organized group preferences. The relative importance of groups and government officials in the shaping of policy, Truman emphasized, was an empirical question, not one to be settled by "preassigning weights and roles" (p. xxv). Analytic pluralists, to be sure, generally avoided using the term 'the state,' but this was not because their explanations were 'society-centered' or because they believed government officials lacked autonomy or importance vis-à-vis societal groups. Rather it was because they doubted, for epistemological as well as empirical reasons, that the myriad institutions and officials of government, particularly in the United States, were coherent enough to warrant a locution that treated the government as a unitary actor with a single will (Ellis, 1992). The same doubts fed pluralists' skepticism of concepts like 'the public interest' or 'the will of the people,' since society no less than the state was a complex mix of rival interests and objectives. In this respect, the modern American pluralists were kindred spirits of the early twentieth-century English pluralists.

Another strain in criticism of American pluralism objected not to its focus on societal groups but to its portrayal of the distribution of power within the United States as dispersed. Pluralists, it was claimed, slighted the severe inequalities in resources and power in American society, and believed mistakenly that the system was self-correcting: that the mobilization of one group would necessarily lead to the mobilization of an equal and opposite countervailing pressure. Pluralists were also said to believe that all important or legitimate interests and opinions were represented within the political system, or even that all groups had substantially equal access to the policy-making process. As the ideological dust kicked up in the 1960s slowly settled, scholars (e.g., Smith, 1990; Hirst, 1987) had begun to recognize that few, if any, of those commonly described as pluralists harbored such naïve views of the political process. The important question, in any event, is not whether it is possible to find someone myopic enough to believe that all groups have equal or nearly equal power, but whether pluralists are logically committed to these propositions. How widely dispersed power is within any given policy domain or in any given place or time is an empirical question that cannot be settled by methodological or theoretical fiat. Nor can it be answered satisfactorily without a comparative perspective: the same distribution of power may be reasonably characterized as either concentrated or dispersed depending on one's comparative referent or on one's normative benchmark. There is no inherent reason that an empirical commitment to the study of interest groups *à la* Truman need predispose the analyst to find any given distribution of political power. Nor need a normative commitment to pluralism, understood as wide dispersion of political influence and power, necessarily predispose one to find pluralism as a sociopolitical fact in any given setting.

The term 'pluralist' is a particularly confusing label because it is often applied to those who conclude that power in a given locale is dispersed rather than concentrated. Pluralism can be a useful term to describe either an empirical reality – one in which there is, for example, widespread dispersal of power, and bargaining rather than hierarchical decision-making – or a normative commitment to such dispersed power, but it does not help to call those scholars who find dispersed power 'pluralists.' When Robert Dahl (1961) finds a pattern of dispersed influence in contemporary New Haven politics, it no more makes him a pluralist than does his discovery of concentrated oligarchic power in early New Haven make him an elitist.

Dahl remains the archetypal pluralist in the minds of many, even though he is not a group theorist on the model of Bentley and Truman. Whether or not Dahl counts as a pluralist, he is

certainly among the keenest students of the dilemmas of pluralism. As a graduate student at Yale in the 1930s, Dahl took a year-long seminar on recent political thought from Francis Coker, who had written the entry on pluralism for the *Encyclopedia of the Social Sciences* (1934). There Dahl encountered Laski and the English pluralists as well as Coker's ambivalent critique, in which he praised pluralists for drawing attention to the importance of autonomous groups intermediate between the individual and the state, while also criticizing pluralists for slighting the need for centralized political control. State control was necessary, Coker argued, not only to referee intergroup conflict but also to protect the "unorganized interests of the general body of citizens" against the organized. Moreover, without active state intervention pluralist group autonomy would result in more powerful groups abrogating the rights of weaker groups. Of particular concern to Coker was the unequal relationship between employers and employees. Dahl amplified his teachers' arguments in *Politics, Economics, and Welfare* (1953). It was one thing, Dahl and his coauthor Charles Lindblom argued, to recognize (as Laski did) that government officials typically could not "enforce decisions by unilateral, hierarchical means" but must bargain with powerful and autonomous groups to negotiate "temporary armistices." It was "quite another to turn this social fact into a prescription of the desirable, and to argue in effect that politicians should not even attempt to exercise 'the last say,' but should turn that power over to national organizations bargaining among themselves" (p. 498). The fundamental dilemma of a pluralist democracy, in Dahl's (1982) view, was that autonomous associations, groups, or organizations are highly desirable and yet also capable of doing great harm if not controlled by a central authority.

Why is pluralism desirable? Advocates of pluralism see autonomous organizations fulfilling a variety of beneficial purposes. Some emphasize pluralism's role in facilitating individual development and self-expression (Rosenblum, 1998), while others emphasize the importance of groups in integrating the individual into society (Nisbet, 1975). Associations are also seen as seedbeds of civic virtue, an enabling environment in which citizens learn the habits of self-government (Putnam, 2000). A different emphasis is evident among those who stress pluralism's defensive political function, as an organizational counterweight to the coercive powers of the central government (Shklar, 1989, p. 28). Pluralism's vital contributions to democratic governance have long been Dahl's primary focus, a concern that became richly salient again as scholars, politicians, and citizens attempted to understand and direct the process of democratization in the former communist countries in Eastern Europe and the Soviet Union. In the absence of vibrant organizational pluralism, the experiences of these nations suggest, it is difficult for formal democratic institutions such as elections, parliaments, and presidents to curb hierarchy and domination (Howard, 2003).

Pluralism may be essential to the functioning of large-scale democracies but that does not mean, as Dahl emphasizes, that pluralism is without disadvantages. To begin with, group leaders may dominate or oppress group members, particularly where the costs of exit from a group are high. Less ominously, the group's elites may fail to represent the opinions of its membership – the elites may be more conservative or more radical, more compromising or more confrontational, than the membership. The English pluralists at times obscured these problems by treating organizations, whether churches or trade unions, as if they were undifferentiated organic wholes with 'real' personalities (even while they denied such a real personality to the state), but American analytic pluralism was rarely, if ever, guilty of reifying groups. Far from treating large groups as if they were homogenous, as is sometimes alleged (Kariel, 1968, p. 168), Bentley and other American group theorists were keenly aware, in Odegard's words, that all groups "are themselves almost infinitely divisible into subgroups whose interests are not always congruent or compatible with one another" (Bentley, 1967/1908, p. xxii).

A second problem with organizational pluralism is that all groups are not created equal: organized interests, all other things being equal, have an advantage over unorganized interests, and some interests are easier to organize than others (Olson, 1965). Autonomy for the lambs may well mean a quick dinner for the wolves. It is the weaker groups, as Schattschneider (1960) argued, who generally have the greatest interest in "enlarging the scope of conflict" by appealing to public authority and thereby modifying the imbalance in private power relations. Recognition that group autonomy may serve the interests of the most powerful groups is a potent argument against the radically antistatist vision of the English pluralists, but not nearly so troubling to the pluralist vision of postwar American political scientists, most of whom were New Deal Democrats. The problems of group autonomy are real, but they need to be counterbalanced with an appreciation for the equally real limits of central control. The articulation of group preferences and mobilization of group interests being absent, a central political authority would define who was a group and whose interests were legitimate. Without group pressures, the state would find it difficult if not impossible to gauge the intensity with which preferences are held. Group autonomy without central control is bad for the lambs, but central control without group autonomy is no better.

Other critics worry that, even if all groups were equal, pluralism may, in Dahl's words (1982, p. 43), "deform civic consciousness" by fostering particularistic or short-run demands at the expense of a broader common good or long-run social needs. Whether civic consciousness is higher or the common good is more closely attended to in those countries or policy domains where interest groups are less prevalent or less assertive is an empirical question, the answer to which is far from self-evident. A related concern is that private associations may be given essentially public functions, thereby removing or reducing democratic control over governmental decisions. One manifestation of this problem is European-style corporatism, in which bargains are worked out between peak associations representing labor, business, and farmers. In the United States, the problem of alienating democratic control may take the form of powerful groups capitalizing on the fragmentation of the system by 'capturing' governmental officials in a specialized policy domain (McConnell, 1966; Lowi, 1969). Dispersed power is not inconsistent with groups monopolizing power in specialized segments of the political system. Again the extent to which this describes accurately the policy-making in any given system or policy domain is an empirical question.

Among the most common criticisms of pluralism is that it was little more than a self-satisfied apologia for American or,

alternatively, Western, democracy. Whether or not those who were associated with pluralist ideas were satisfied with the state of democracy in America or Western Europe, pluralism as a normative vision is not inherently conservative. Hirst (1989), for instance, uses pluralist ideas to launch a blistering critique of the British political system, particularly Parliament's claims to unlimited sovereignty. Measuring Western democracies against an exacting yardstick of pluralist principles, Hirst finds severely wanting not only the West's narrowly plebiscitarian vision of democracy, in which "the people periodically choose who are to be their elected masters" (1997, p. 1), but also the over-centralization of the provision and delivery of public services. Taking pluralism seriously, Hirst maintains, means radically reshaping governance, not only in the nation state but also in international institutions such as the European Community. Dahl himself draws upon pluralist ideas to argue for a dramatic devolution of power to cooperatively owned economic enterprises. And in much of the non-Western world, even the tamest of pluralist ideas can pose a subversive challenge to entrenched state power and economic privilege.

Writing in the 1968 *International Encyclopedia of the Social Sciences*, Henry Kariel wrote an obituary for political pluralism, which "as an ideology … only lingers quietly as a submerged, inarticulate ingredient of Western liberalism" (p. 168). Almost half a century later, it is clear that reports of pluralism's demise have been greatly exaggerated. Particularly as a normative vision, as an antidote to plebiscitary democracy and to centralized state control, political pluralism has shown renewed appeal and relevance across the globe in the twenty-first century.

Pluralism and Tolerance

Abstract

This article is concerned with one of the most important characteristics of modern society – pluralism, and with the concept, which gives an answer to the various challenges pluralism poses – tolerance. After tracing the idea of pluralism, I focus on the various implications the fact of pluralism has for contemporary liberal societies. I then examine the concept of tolerance both historically and systematically, distinguishing between active and passive tolerance as well as between personal, political, and social tolerance.

One of the most important characteristics of modern society is its pluralism. Because of the challenges and problems pluralism raises, tolerance is needed as a counterpart. Though the idea of tolerance has a long and complex history, today it can primarily be understood as an answer to the challenges of pluralism. As pluralism has different aspects, the same is true for tolerance. Whereas pluralism emphasizes the diversity of equally entitled, free groups, tolerance stresses the 'live and let live' of others' liberty.

Though pluralism, and tolerance as its counterpart, are important concepts to explain modern society, they are one-sided concepts, which have no absolute value, but only a relative one, since beyond the plurality of values and life-forms, something has to be shared by all human members of society in order to prevent its dissolution. Pluralism and, correspondingly, tolerance cannot justify themselves – in both cases, the more fundamental ideas of freedom and justice are necessary for their justification.

The Idea of Pluralism

Pluralism can be understood in a metaphysical sense as designating those philosophies that allow for a diversity of entities in their explanations of the world, as did the Enlightenment-philosopher Christian Wolff (1720). Kant contrasts egoism with pluralism, which he understands to be "the way of thinking in which one is not concerned with oneself as the whole world, but rather regards and conducts oneself as a mere citizen of the world" (1798/2006: p. 18).

The pragmatist philosopher William James maintained the existence of an infinite number of limited facts, connections, and systems that are in constant flux; which always lead to new relationships and structures; and for the cognition of which, fixed categories and criteria do not exist, only perspective orientation points (James, 1909). Pluralism can also refer to the methodological neutrality of the social sciences of an empiristic orientation, to the multiplicity of cultural forms, from which "all sociology has its starting point" (Scheler, 1980: p. 25). Today, the term is primarily understood in a social and political sense in which empirical and normative elements converge.

Empirical and Normative Elements

Empirically speaking, pluralism denotes the diversity not only of confessions and religions (religious pluralism), but also of social groups together with their lifestyles (social pluralism), of basic values (pluralism of value), and of the powers, which determine politics (political pluralism). For this many-dimensional diversity, our lifeworld has primarily benefited from the religious wars of the Reformation, the European Enlightenment, and the Bourgeois and Industrial Revolutions. Through those factors, a process of differentiation was set into motion, which dissolved both the relatively homogenous and stable relationships of the so-called old-European societies and the connection between church and state. Moreover, this process brought forth open societies, the numerous and constantly expanding groups of which had their own interests, convictions, and manners of conduct. More recently, pluralism has gained a new momentum through the process of globalization (Höffe, 1999/2007), in particular also through migration movements, many refugees, and those looking for asylum.

Second, pluralism purports – and here one finds its normative content – that diversity and difference is acknowledged and approved of; all functionally different groups are equally entitled to develop themselves in a free and unconstrained manner.

The notion of pluralism is of particular relevance in modern democracy theory (Fraenkel, 1979; Oberreuter, 1980). It is considered here as a critical notion, namely as that central mediative category between the individual and the state, with which the liberal atomization of individuals just as the omnipotence and an all-encompassing capacity of the state are rejected. In a democracy, the empirical thesis of pluralism claims, many-faceted powers are at work, which, on the basis of a fundamental consensus over institutionalized arbitration with and against one another, struggle for influence and importance. As far as the normative content of pluralism is concerned, various social forces, notwithstanding their differences in content and function, have the same right to engage themselves in the political process by the means of, e.g., voting, of contributions to public deliberation, or by addressing themselves to members of parliament. These forces include trade groups, unions, and employers' associations, scientific organizations, churches, and political parties, and even civil action groups. Politics is not derived from the conception of a common good which is clearly recognizable, prior to all political confrontations and which does justice to all parties concerned. Political decisions are a result of the constant dispute between competing interest groups which have to mutually monitor one another and, in constantly new coalitions, 'scuffle' together into a compromise which might be accepted by a majority.

The Critique of Pluralism

The criticism of the idea of pluralism is leveled partly at its empirical thesis and partly at its normative content; the normative criticism pertains to either pluralism of value or political pluralism.

Pluralism of value becomes visible in the form of the ideologically neutral state. It is reproached with relativism and even nihilism because it does not even acknowledge certain very general values as binding and is held responsible, therefore, for the crises of meaning and orientation, which threaten contemporary industrialized societies. Pushed to the fore, the ideologically neutral state will abolish itself, because it cannot legitimize the framework in the limits of which various powers are capable of freely expressing themselves.

The most significant criticism of *political pluralism* stems from Carl Schmitt (1927) and his followers, who fear the centrifugal, 'anarchistic' tendencies of pluralism. Through the openness and insecurity of pluralistic democracy, the state's power of decision making is left crippled; moreover, the compromises resulting from such a situation correspond to neither moral nor economical ideals of sound politics.

Supporters of the critical theory hold pluralism for desirable, but contest the existence of the empirical presuppositions for its realization. They point to the socially underprivileged, who are either effectively shut out of participating in the bargaining process of weighing competing interests, or are, at least, clearly at a disadvantage when up against more powerful organizations. The normative idea of an equal right for all groups is, therefore, rather a postulate than social reality. Other critics maintain a 'standardization of subjects', who are no longer capable of an autonomous definition of their interests and, hence, of a genuine pluralistic differentiation. Where a free concert of interest groups once existed, one now finds bureaucratic apparatuses in their place, the internal dynamics of which dominates the political scene.

Pluralism and Liberal Democracy

Political pluralism presupposes two conditions as given. On the one hand, all interests and the groups that represent them should have equal rights in public deliberation and in the process of political will-formation; on the other hand, the common good should realize itself through the struggle of interests between groups of equal rights. Even in developed democracies, both conditions are fulfilled at best in approximation. For in pluralistic society, citizens with their interests and convictions have no direct access to politics; their access stands in need of mediation through clubs, organizations, and political parties. In this manner, interests and convictions do indeed gain political power, however at different levels of intensity. The mediation of interests and convictions very often leads to perceptible distortions of their influence.

Due to varying historical or social conditions, many interests and convictions are represented more powerfully than others. The explanation of this fact might be seen in the tighter organization of certain associations, to the better support by more potent moneylenders, or to the fact that such groups have attractive media at their disposal, or better relations to the mass media. An equality of rights in modern times is not realized through the abolishment of legal privileges, characterizing hierarchical feudal or class societies. Pluralism does not simply describe our social and political reality. It is to a significant degree really a postulate, according to which societies need to be changed and modified.

A modification within pluralism, however, is possible only to a limited extent: first of all, because powerful groups do not freely relinquish their predominance; second, as can be observed sociologically (Olson, 1965), many interests are much easier to organize than others, which may lead to the superiority of certain economic groups (employers as much as employees). Furthermore, mergings and the oligarchical tendencies within organizations endanger civic freedom, the essence of pluralism. Dependence on the government gives way to dependence on both the bureaucracy of associations and its functionaries. Finally, even a fair arrangement between a plurality of interest groups does not simply lead to the realization of the common good; for, as a rule, long-term interests get the worst of short-term interests, just as general interests get the worst of particular interests. It is for this reason that the protection of the environment is so easy to push aside.

In taking an overview of these arguments, one must neither adhere to a conspiracy theory, nor to an extreme criticism of capitalism, in order to preserve a residue of skepticism with regard to the affirmation of an empirically existing pluralism. Hence, the plurality of intermediary groups is without a doubt a pillar of freedom; a pluralistic society is invariably better than a nonpluralistic one; and pluralism itself an important structural element of the liberal–constitutional democracy. Nevertheless, pluralism alone cannot warrant its own significance; it is only a helpful not in any way sufficient organizational form of freedom and equality. One should not easily identify pluralism and liberal democracy because the notion of pluralism brings to light only diversity and competition, and not the complementary elements of commonality and cooperation.

A liberal democracy consists not only of the coexistence and confrontation of a diversity, but also of the regulation of coexistence and confrontation. Regulation brings about community: the mutuality of problems to be solved and, in particular, that fundamental (constitutional) consensus, which defines the normative content and the rules of pluralism. In this manner, pluralism shows itself to be a one-sided, nondialectical notion that stresses plurality instead of unity, competition instead of cooperation.

A Relative Pluralism

Because empirical and normative elements converge in the notion of pluralism, the normative valuation has already begun in the empirical thesis. It is continued with a *pragmatic* consideration: the decentralizing of political power, the institutional and social separation of the process of will formation, just as the diversity of convictions and manners of conduct increase the chance of an efficient coexistence, in which superfluous frustrations and conflicts decrease.

The comprehensive moral evaluation begins with an ethical–anthropological insight. Because of its lack of instinct and a wanting specialization of organs, mankind is not fixed to definite manners of conduct. Due to its capacity for language

and reason, mankind is much more reflective in relation to its doings and omissions; this not only enables it to act freely and responsibly, but also constitutes a particular challenge. Therefore, mankind, be it as individual, a small or a large group, has the task and the right to develop its own convictions and practices, and to determine and pursue a particular conception of a good life. Different convictions and practices are to be expected, on account of the historical factors under which this process of personal as well as social self-determination takes place. The form as well as the results of self-determination are limited by different perspectives, and a single individual cannot lay claim to the unconditional 'truth' for himself (Rawls, 1993: p. 36). In the pluralism of interests, of values, and of life plans, the wealth of human self-realization is expressed just as well as the limitation of every concrete design.

On the other hand, different groups are already related to each other through the social division of labor; but the division of labor represents only one of the many aspects that make mediation necessary. Within one's own group, the recognition of interests and convictions is commonplace. However, with regard to other groups, these interests and convictions stand in both competition and conflict. Because the solution of conflicts is not secured by instincts, there exists the danger of collective self-destruction of mankind. In order to check this danger and, at the same time, to avoid a crude sort of social Darwinism that makes the weak even weaker and the vital and cunning even stronger, general obligations are necessary, which guarantee a humane and just management of conflicts. For that reason, not an absolute and merely a relative pluralism that develops in the context of fundamental commonalities is really desirable.

Pluralism of this sort can encounter the suspicion of being relativistic and nihilistic. Even if modern societies are skeptical of a timelessly valid code of values, even if they do not confer infallibility upon a particular personal, political, religious, or intellectual instance, they nonetheless need at least a few generally valid obligations removed from the opposition of particular designs of faith and existence. Therefore, human rights are accrued a particular meaning: as the personal right to liberty, the political right to participation, and as social and cultural rights, they are the condition and expression of the mutual recognition of fundamentally equal persons. Therefore, human rights refer to those claims which every individual may legitimately raise: they belong to a sphere beyond a legitimate pluralism and which every legal order, every state, especially pluralistic democracy owes to each individual. Through human rights, even those minorities that come off badly in the pluralistic struggle of competition are protected (Rawls, 1971; Höffe, 1987/1995).

The Idea of Tolerance

Originally, tolerance does not refer to tolerating somebody, but something. As a passive form of bravery, tolerance originally means the ability to suffer in the face of negative experiences: a patient enduring of bad things such as pain, torture, or strokes of fate. It is only later, under the conditions of pluralism that the meaning of the concept changes and now applies to tolerating the stranger, especially the stranger adhering to other religions and confessions. In this way, an attitude of how to live one's only life is transformed into a moral attitude how to treat others. The original concept of tolerance as one of individual ethics is transformed into a virtue of social ethics, a virtue of individuals (personal tolerance), communities (political tolerance), or cultures and societies (social tolerance).

Ever since the concept of tolerance changed into meaning the endurance of otherness, it is inevitably linked with pluralism as well as relativism. If all human beings belonged to the same religion, no religious tolerance would be needed, and if everybody lived the same way, no social tolerance would be required. It would also not be required in a society in which everything is totally arbitrary: if every conviction and lifestyle counts the same and if they all are equally valid, tolerance loses its area of application. Tolerating the others not only presupposes otherness; one's own otherness needs to be important to oneself, and the other's otherness thus objectionable. A person is not tolerant if he or she simply takes recourse to an attitude of detached indifference. Rather, the tolerant person actively tolerates persons with other convictions and another lifestyle. Tolerant is he or she who, contrary to mere indifference, actually experiences impositions, but, contrary to intolerance, endures them.

Its Origin in Religious Tolerance

Like the general principle of liberty, the particular principle of tolerance found its general recognition only after long intellectual and sociopolitical debate. In this context, religious tolerance plays a particular role (Püttner, 1977).

Many people consider tolerance to be an invention of modernity. A central principle, however, was developed already one and a half millennium before modernity. In the ancient Orient, religion, society, and the state were closely intertwined. In contrast to that, the demand from the New Testament "Render to Caesar the things that are Caesar's, and to God the things that are God's" (*Matt.* 22: 21) points toward a certain separation. The *Edict of Milan*, inspired by this demand, already in 313 AD lays down a corresponding right: Every person may believe what he or she wants. Because of that, earthly punishments for religious offenses are to be prohibited.

Since polytheistic religions make a lesser claim to truth than monotheistic ones, they do not face many difficulties as far as the toleration of diverse religious beliefs is concerned. Pre-Christian Rome allows all conquered peoples to practice and even propagate their own cults. Yet the Christians were excluded from the rule of tolerance, but not for religious reasons; from their refusal to observe the transmitted gods, one fears a backlash within the entire commonwealth.

As long as the Christians are persecuted, they appeal to the Roman Emperors, referring to the rights which all mankind are due: that freedom of religion is granted internally and externally. But after Christianity is promoted to the status of a state religion, it soon forgets this demand and its underlying principles contained in the New Testament: even the principle of reciprocity (*Matt.* 7: 12; also *Tob.* 4: 16); the sermon on the mountain; the parable of the weed under the wheat (*Matt.* 13: 24–30, 36–43); Jesus' conduct in general of welcoming, but not of forcing his imitation; moreover his magnanimous attitude toward sinners; finally, the apostle Paul's conception of freedom of religion as free from enforcement and his

admonition to mutual tolerance (*Col.* 3: 12f.; *Cor.* 1: 4,12; *Cor.* 2: 11.1; and *Gal.* 5: 1.13).

Whereas the *Edict of Milan* leaves religious belief to its practitioners and, moreover, differentiates between state and religion, the swift rise of schisms and heresies fills the bishops with such alarm, even in the patristic times, that they begin to bind, as in the ancient Orient, religion closely with politics. Especially the conversion to a foreign cult is punished to the same extent as capital crimes and the disruption of civil order.

Granted, medieval Christendom should not to be considered intolerant through and through (Patschovsky, 1998). Because it regards the transmittance of faith as a matter of free conscience, the conversion of pagans by force represents a clear exception. Jews are generally and, often, truly tolerated; and for a long time the Christians live in mutual tolerance with the Muslims. But, the heretic in Christendom, accused of both arrogance and impertinence, was considered, like the Islamic apostate, as it were, an outlaw in the eyes of the law. In the eleventh and twelfth centuries, capital punishment extends to the heretic and is maintained until well after the Reformation. The foundation of medieval intolerance, the all too intimate fusion of *Sacerdotium* and *Imperium*, of spiritual and secular matters are all well preserved in Protestant countries, more likely being advantageous to the state than to the church.

In the 'confessional age' (the age of the Reformation), the idea of (religious) tolerance has to be reestablished; and it is effected only after hefty intellectual debate and painful political experience. In order to encourage the victory of tolerance in the form of the religious neutrality of the state, the mutual autonomy of the state and the church, a few fundamental insights first have to be (re)attained. At first, the pragmatic consideration of the 'greater benefit', the fact that in most cases mildness is better suited than force in order to gain back 'lost souls'. Then one also has to reach the insight that the New Testament is based on tolerance and love, moreover, that not only the conversion but also the retention of faith is both an act of freedom and of mercy, and for that reason, cannot be enforced; furthermore, that the church is a free communion, whose task is to be fulfilled in the spiritual, not in the secular realm, and that for this task every possible constraint is useless, as it would at best lead to a feigned and not to a real recognition of faith.

The way for this new form of tolerance is prepared by Christian humanists like Dante, Marsilius of Padua, Nicolaus von Kues, and Sebastian Castellio, who reject all acts of violence against religious dissidents. However, they are still fixed to ideas of religious unity within Christendom, and, therefore, they search for a peaceful reconciliation by way of religious forum and dogmatic compromise between rivaling confessions. On the contrary, mystic spiritualists as well as some religious cults engage themselves directly for the religious liberty of each individual; they do this by appealing to the Holy Ghost, who forbids every form of slavery in the realm of the religious, including that of the institutional church.

Whereas no lasting success is allotted to either of these thoughts (peaceful reconciliation or religious individualism), the second half of the sixteenth century sees the problem shift from the religious to the 'secularized' level. Theological arguments are succeeded by considerations of politics and natural right, occasionally even of economics; unsuccessful reconciliatory talks give way to efforts of toleration, in which the denominational heterodox gains ground.

Starting in France, where the preservation of the nation is considered more important than the reestablishment of religious unity, the idea of civil tolerance, which unambiguously differentiates between the aims of the state and the aims of religion, is established against the rule of 'one confession, one law, one king'. With the idea of the confessional, later the religious neutrality of the state, the bloody experiences of confessional civil wars that, at the European level, ended in a stalemate, are finally digested. Consequentially, the relative autonomy of the state and church/religion and, with that, of confessional pluralism, is acknowledged as a necessary condition for political, even physical survival. Nevertheless, the numerous edicts of tolerance, which follow on the Peace of Augsburg (1555) and the Edict of Nantes (1598), are issued only reluctantly. In auspicious circumstances, as in France (1685), the edicts are repealed or, as in Great Britain, where the Catholics remain second-class citizens until the nineteenth century, they are not valid for everyone from the outset.

Because intolerance endangers the free development of business and trade, Europe and North America also have economic reasons to thank for the following two phenomena: that religious liberty does indeed assert itself in the end, and that the remnants of the medieval connection between the state and the church are vanquished. The European Enlightenment, however, plays a particular role in the ultimate victory of the principle of religious tolerance. Inspired by the idea of universal human reason and liberty, such figures as Grotius and Spinoza, Milton, Locke and Voltaire, Lessing (*Nathan the Sage*), later also Schiller (*Don Carlos*) turn to the remnants of dogmatic and political intolerance within the high church and to their corresponding, amalgamated states; moreover, they lay claim to religious liberty as a fundamental personal right to liberty. But, even those propagating the Enlightenment as a rule exclude atheists and nonbelievers from the idea of tolerance, granted, as with Locke, not out of religious but rather out of political reasons; for, whoever does not believe in God cannot take a legally admissible oath.

That religious freedom is established in the end is just in part due to a philosophical insight. The primary reasons for this establishment are to be found in the bloody religious and civil wars, as well as in economic and scientific developments – because intolerance threatens the free flourishing of trade and industry, as well as that of science and art. Tolerant states such as Brandenburg-Prussia and the Netherlands consequently flourish economically as well as culturally. Thus, already a well-considered self-interest calls for tolerance.

The justification from human dignity, however, is normatively more fundamental. This justification declares every human to be a free and equal person, supplied with the right to develop and pursue own convictions and beliefs. Recognition of corresponding rights for every other human being is, naturally, part of this principle. Tolerance ends where freedom and dignity of others are infringed.

The justification from freedom and dignity of every human being thus entails both: a measure for tolerance as well as a criterion for its limits. By making the demand that nobody should be allowed to a liberty, which cannot be allowed to every other person, as well, tolerance refuses to submit itself to

injustice. In cases where freedom and human dignity are threatened, tolerance transforms itself into critique, accusation, and protest. Paradoxically speaking, tolerance meets intolerance with intolerance.

Passive and Active Tolerance

The idea of tolerance kindled itself on the freedom of religion in Western Christianity. In our advanced, secularized world this idea no longer represents a special problem with regard to the social interaction of diverse confessions and religions. Tolerance is often enough primarily called for in relation to beliefs, which are socially, politically, and culturally differentiated. Thereby, a weaker, more passive form of tolerance, the mere toleration of otherness, is to be differentiated from a stronger, more active, and creative form, the openness to differences, yes, even to their candid recognition.

As pluralistic democracy cannot arise nor continue to subsist without the mutual toleration of otherness, tolerance is, at least in the weaker form, a fundamental principle of modern states (for developments see Lecler, 1955; Lutz, 1977; Becker, 1996). However, tolerance is not only necessary under the condition and in favor of a political pluralism. If not always immediately and distinctly perceptible, there are nonetheless differences among mankind: in need, talent, and interest; in taste and in sociohistorical origin; moreover, in the perception and interpretation of the personal or social situation in which one lives. Nor is one free of faults, prejudices, or mistakes. Therefore, at least passive tolerance is held to be a universally valid posture with regard to the civilized intercourse of mankind; it is through just such relations that the coexistence in marriage and family, in industry, in society, in the government, even between states is made bearable as well as efficient. So, even an enlightened self-interest speaks in favor of tolerance.

However, the core dimension of tolerance is, with that aspect, not yet achieved. Its stronger form, the candid recognition of the other and otherness, is grounded in the dignity and the liberty of every human being. Therefore, tolerance consists not only of that forbearance of the peculiarities and weaknesses of one's fellow man, which can be solicited from them and freely granted to them. As the coexistence of individually responsible persons with equal rights is not possible without reciprocal recognition, tolerance is a fundamental condition for the justice of mankind's coexistence in freedom; and, as a condition of justice, it is a claim that can be refused to no one.

For active tolerance, not merely the practical (moral–political) principle of liberty but also a theoretical interest in truth be adduced. Human perception being limited, the open debate of different opinions offers a better chance for establishing truth than the 'intolerant', namely, dogmatic and of a conviction considered infallible (Mill, 1989).

Tolerance, in any case, appears in two steps. The elementary step, which is in fact only a prestep, is passive tolerance. Here, tolerance is merely enduring the others, and often is combined with contempt. The second step, however, is where true, active, and authentic tolerance resides: Active tolerance is not content with merely accepting others unwillingly. This kind of tolerance rather overcomes mere acceptance and voluntarily and freely affirms the other's values and lifestyles, as well as their freedom and liberties. Thus, active tolerance is no fig leaf behind which moral indifference lurks: It is founded in the recognition of one's own value, one's self-esteem and self-respect.

Personal, Political, and Social Tolerance

Religious liberty is only one example that brings to the fore the specific intellectual and political difficulties that have to be overcome in order for the principle of tolerance to become historically significant. This principle, which goes beyond religious liberty, takes primarily three different forms: tolerance as (1) a personal attitude, (2) as a political principle of the state, and (3) as a principle of a society or culture. All three forms mutually supplementing and yielding one another.

Whoever affirms the self-determination (the right to life, the will to development, and the liberty) of the dissentient is realizing the individual attitude of tolerance: personal tolerance. Only when one has one's own convictions, can one speak of recognizing an 'other'; and only there, where one does not indulge in indifference, or in the type of cynical nihilism that plainly lets everything pass as valid, including even gross injustice, can one speak of this particular attitude. Tolerance does not mean the fig leaf, behind which moral indifference and intellectual weaknesses conceal themselves. It is a critical autonomy which does not even allow certain conflicts to arise in coexistence, especially not in situations of competition; and which does not go through the inevitable debates and quarrels with the inexorable severity of a religious war. Whoever is tolerant no longer pursues a life, which is founded upon self-assertion through violent conversion, or through the surmounting of adversaries. He or she endeavors to establish a communality on the basis of civil equality and communication to which the following qualities belong: the ability to listen, the capacity to take others seriously, and finally the willingness to let oneself be taught by new situations and new information. Tolerance is then accomplished by the willingness and ability to sympathize with the views and lifestyles of others.

Like pluralism, tolerance too is grounded in the following factors: the understanding that no one is entirely free from faults; the knowledge of the wealth as well as the perspectival limitations of every concrete instance of self-realization; and the insight into the limits of human knowledge. Tolerance, however, originates primarily in the recognition of the other as a free and equal person, who, on the basis of the inviolable dignity of mankind, has the right to form his or her own opinions, and to live according to them alone, or with like-minded individuals – provided that the exercise of this right does not encroach upon the same right of all others. The virtue of tolerance is one of the most important political virtues of a democratic citizen (Rawls, 1993: p. 194).

As tolerance does not represent an end in itself, but rather a condition and an expression of the liberty and dignity of mankind, it terminates at the point where liberty and dignity are violated. Tolerance does not consist, as Marcuse (1965) fears, of the stabilization of existing social states, in the preservation of the status quo, and even less of the (masochistic)

acceptance of injustice. Wherever the liberty and dignity of mankind needs to be protected, tolerance crosses over into accusation, criticism, and protest. The obligation to impose on no one a limitation of his or her liberty, which is not imposed on all others in the same manner, can be considered a criterion for the limits of tolerance. The highest principle of justice consists of this criterion of an equal liberty, which is primarily spelled out in terms of human rights.

Because the justification of tolerance is found in liberty and justice, it cannot be left to the discretion of individuals and political powers. Its recognition is not only a voluntarily assumed attitude, but also a duty of justice, the implementation of which the legal order, the state, is responsible. It is therefore a political task to institutionally guarantee basic elements of tolerance, such as human rights. The first task of tolerance as a principle of the legal order and the state is therefore found in the positivation of human rights and their recognition as basic rights (personal right to liberty, political right to participation, and social and cultural rights), or, as the case may be, as fundamental aims of the state (liberty, democracy, and welfare state).

As long as human rights are only recognized by coercion, tolerance remains nothing more than an acceptance accompanied by contemption toward those who think and live differently. In order to guarantee the stronger form of tolerance – coexistence based on mutual respect – tolerance as a duty of justice has to be acknowledged on its own terms; moreover, it must become through continuous practice a component of one's personal character, a genuine attitude. Tolerance as a political principle is only accomplished when this duty of justice is freely accepted as a moral virtue of the citizen.

Communities are tolerant in a weaker and passive sense if they simply endure minorities. They are, however, tolerant in an active sense if they affirm and grant public legal security to these minorities – as it is custom within liberal democracies. For a society to be tolerant, more needs to be the case. A social tolerance that reaches beyond the political level refrains from any pressure of conformity; it even allows for eccentric lifestyles provided they are nonviolent and peaceful.

At the international level, tolerance demands the mutual respect of different cultures and traditions, instead of valuing European culture or American lifestyle as the ideal of the development of all civilization and to devalue all other forms as primitive and barbarian. This type of respect was articulated first in Herder's (1774/2004) and later in Hegel's (1821/1991) theory of the 'spirits of nations' (*Volksgeister*), according to which different social and cultural patterns in which different peoples think and live assert themselves in the course of history. As these forms are coherent, they justify themselves to this extent.

One facilitates the recognition of other cultures' intrinsic value whenever one looks not only to that which divides but also to that which binds, that is, universal human attitudes such as readiness to aid, civil courage, and honesty. These commonalities are not only acknowledged as morally binding in the Christian West, but also in the most diverse of societies and epochs. The tolerance that began with religious liberty is accomplished only at the point, where the colorful abundance of personal and sociohistorical self-realization is freely acknowledged as both a task and a chance for creative humanity.

A Classification

Making use of the concepts of tolerance discussed so far, we can establish a classification of cultures and religions. Needless to say that within this classification, cultures are not measured by their cultural quality and religions are not measured by their religious quality. Instead, this classification uses the willingness to intercultural coexistence as a measure, which arises from an attitude of tolerance.

(1) At one extreme, there are those cultures that are as good as *helpless* with regard to modern tendencies and have no means to hold on to their distinctiveness – e.g., inhabitants of the rain forests and other indigenous people. If these cultures are not left to their own, they will be destroyed. (2) Other cultures like the Mennonites and the Amish people are *defensive*. Content with themselves, they are able to isolate themselves from others, provided that they are left alone. (3) *Reciprocal* cultures exist within a reciprocal give-and-take. (4) *Peacefully expansive* cultures give far more to others that what they adopt from them. They do not use any force or coercion, but are content with the attitude of a peaceful suggestion. (5) A *resentment–aggression* does not force itself upon others, but it isolates itself with violent means. Frequently, such a culture reacts with hatred toward the other; inner violence transforms itself into outer violence. (6) At the other extreme, finally, there *are aggressive–expansive* cultures, which force their elements upon others – not only religion, but also their language, their system of law and their custom, as well as their corporate culture.

Abstract

Karl Paul Polanyi was born in Vienna in 1886, received his doctoral degree in Budapest in 1912, and ended his career at Columbia University lecturing in economic history and coordinating research into the origin of economic institutions. The major question of Polanyi's substantive view is how to identify the place of economies in societies. Embeddedness, according to Polanyi, is related to the fact that an economic actor is a social being, with a mixture of motives, serving to attain social recognition and social goods. Economy can therefore be interpreted as processes of production, transport, transactions, and disposition. Institutions lend unity and stability to these processes, which can be studied via the forms of integration: reciprocity, redistribution, and exchange. Markets are integrated into a dominant system only in exceptional historical cases. Substantivism became a chapter in the history of sociology and anthropology; Polanyi's embeddedness concept is a point of reference in economic sociology. Polanyi also influenced research on state and economy as well as socialist and postsocialist studies.

Biographical Notes

Karl Paul Polanyi was born in Vienna on 25 October 1886 to Michael Pollacsek and Cecile Wohl. They had married in 1881 and had six children: Laura, Adolf, Karl, Michael, Zsófia, and Paul. Karl became a recognized scholar in sociology and anthropology while Michael in physical chemistry and social sciences. Polanyi's father worked for the Swiss Railways and Vienna's Stadtbahn, before setting up on his own as a railway builder in Hungary. In the 1890s, the family moved to Budapest where Karl Polanyi began his secondary studies in the model school of the teachers' training institute in 1898. At the turn of the century, Polanyi's father's business went bankrupt and after indemnifying the creditors, the family was impoverished and the father was forced to take a job abroad again. In spite of that, there was lively intellectual activity in the parental home in Budapest. Polanyi's mother, Cecile Wohl, organized a literary salon attended, among others, by Oszkár Jászi, György Lukács, and Karl Mannheim. After finishing secondary school in June 1904, Polanyi enrolled in the Faculty of Law in Budapest University. He lost his maternal grandfather and father in 1905, both of whom had especially deeply inspired him. After attending courses in Vienna and Budapest, he took part in organizing demonstrations for the progressive thinker Gyula Pikler, a professor of the Philosophy of Law in 1907. Polanyi obtained his Doctoral degree on 26 June 1909 from Bódog Somló at the Kolozsvár (Cluj) University. In 1908 he became president of the recently formed Galilei Circle, a student body set up to disseminate the scientific world view in readings and debates, without – as Polanyi later self-critically recalled – being politically involved. He qualified as a lawyer in 1912 and began to co-edit the review *Szabadgondolat* (*Free Thought*) in 1913. His writings argued for free education and were devoid of the influence of the church. In 1914, Polanyi was involved in establishing the Radical Party, of which he became the secretary.

However, the next year he was sent to the front and discharged 2 years later as disabled. During the liberal Károlyi government of 1918, he was a member of the legal committee of the People's Council in Budapest and of the Students' Council. However, on the eve of the Hungarian Soviet Republic in 1919 he delivered a speech against the dictatorship, and then migrated to Vienna. He soon underwent a serious operation followed by a lengthy recovery. He was working on a voluminous unpublished work, *Behemoth*, concerned with the destructive capacity of science. In this he says that the future is constantly being remade, therefore it cannot give validity to our actions in the present.

In addition to Ludwig von Mises, Jakob Marschak, Felix Weil, and others, he contributed to the theoretical debate about the possibility of the planned economy in which he elaborated a proposal to solve the problem of 'Sozialistische Rechnungslegung' on the basis of the principles of guild socialism. He met a well-known figure of the revolutionary students' movement, Ilona Duczynska, in 1920. They married and had a child, Karoline Helene (Kari) in 1923. In Vienna, Polanyi first worked for Hungarian papers (Bécsi Magyar Ujság and Bécsi Kurir), and then from 1924 to 1933 he contributed to the Österreichische Volkswirt. Having lost his job because of the crisis and the rising danger of National Socialism, he emigrated to England where he was one of the masterminds behind the Christian Left movement, and concentrated on criticism of the essence of fascism.

This time he joined the Workers' Educational Association and the Extra-Mural Delegacies of Oxford and London, lecturing mainly in general economic history and social theory. His lectures focused on the shift from laissez-faire to regulated capitalism, when state and industry began to interpenetrate, and interference of government with the captains of industry became regular.

In 1940 he became a British citizen, but from that year, he was resident lecturer at Bennington College in the USA and toured America with lectures. He also worked on *The Great Transformation* first published in 1944 (Polanyi, 1957 [1944]). After returning to the UK during the war this book earned him the post of visiting professor at Columbia University, New York, in 1947. He lectured in economic history and coordinated research into the origin of economic institutions. These efforts were summed up in the posthumously published *The Livelihood of Man* (Polanyi, 1977). He continued to do research with a team after his retirement in 1953, publishing their findings in *Trade and Market in*

the Early Empires (Polanyi et al., 1957). The posthumously published *Dahomey and the Slave Trade* (Polanyi, 1966) was another result of the cooperation.

The family settled in Canada as US authorities had denied an entrance visa to Polanyi's wife. In 1963 they visited Hungary, where Polanyi gave a lecture about American economic sociology. He died of a stroke during the night of 23 April 1964 in Toronto, Canada.

The Substantive View

The major question of Polanyi's substantive view is how to identify the place of economies in societies (Polanyi, 1947, 1977). He argues that economic activity is embedded in the social and cultural setting and that the predominance of price-making markets does not apply to most primitive, archaic, or even contemporary economies. He therefore taught that the changing place of economies could be best described by combinations of comparative concepts that shed light on the alternative logic of economic reproduction. Polanyi's substantive theory was discernible in its essentials in *The Great Transformation* (Polanyi, 1957[1944]) and in the lectures he wrote in preparing it. The book, a critique of the market system, is a derivative of historical knowledge and skills accumulated in political journalism. This is borne out by his later remark that he had two aims with the work: to transfer the more combatant Austrian workers' culture into the English labor movement; and give an up-to-date criticism of capitalism, providing intellectual support to Roosevelt's New Deal. In Polanyi's view, the imminent problem of the market system was not the existence of markets but that land and labor were turned into commodities by this system. The analysis of the so-called Speenhamland law, temporarily hindering the creation of a competitive labor market as well as of the ensuing welfare acts, revealed that welfare legislation failed to efficiently remedy the mass impoverishment paradoxically entailed by growth and could only delay the emergence of a labor market from masses of wage workers.

The book was written during World War II, parallel with Hayek's *Road to Serfdom* (Hayek, 1976[1944]) and after Burnham's *The Managerial Revolution* (Burnham, 1960[1941]). While Hayek argued that deserting the road of self-regulation leads to fatal social deformation, Burnham envisaged the inevitable predominance of managerial-elitist hierarchies with the growing autonomy of control functions. Polanyi focused on the double movement of laissez-faire economy and self-protective society. He derived the respective distortions from the market system and from the degeneration of society's defensive mechanisms. At this point he basically agreed with Owen, that the institutional system was unfavorable to social happiness, because it produced unsettled, crude, migratory types of laborers and capitalists without self-esteem. From time to time he turned back to this normative problem of good society in his lectures and writings (Dalton, 1968; Polanyi, 2003[1959]).

What constitutes the continuity between these and his earlier ideas was the criticism of the market system, the rejection of faith in advancement, the doubt about interpreting class interests as material interests, and the stress on nonanonymous historical processes resulting in the market system.

These ideas can be detected in the study 'Our obsolete market mentality' (Polanyi, 1947) and in the volume *Trade and Market in the Early Empires* (Polanyi et al., 1957). However, the emphasis in the former is on the more accurate clarification of the concept of embeddedness, and in the latter, on the empirical analysis of primitive and archaic economic formations.

Embeddedness, according to the substantivist view, is related to the fact that an economic actor is a social being, with a mixture of motives, serving to attain social recognition and social goods. His economic efforts are therefore usually subordinated to these goals. Hunger and gain are not universal motives – Polanyi and his colleagues argued – thus the scarcity postulate, the cornerstone of formal economics, is inadequate. As indicated in the title of Polanyi's key study, economy can be interpreted as an 'instituted process' in a substantive sense. The term process refers to 'location and appropriate movements,' that is production and transport on the one hand and transaction and disposition on the other.

Institutions, as he put it, lend unity and stability to these processes, which can be approached via the forms of integration. Among these reciprocity presupposes the symmetry of groups, while redistribution is dependent upon collecting and distributing goods or disposal over them, hence it implies centricity. Exchange, in turn, depends on the existence of price-making markets. Not every exchange has integrative significance. Polanyi argued that neither simple operational exchange nor decisional exchange at a set rate integrate the economy, whereas bargained rate exchange does. The forms of integration are not arranged in phases, in stages of development as do the types of List or Bücher (Polanyi, 1968); apart from the predominant forms, others are also present, constituting varying combinations. Trade, money, and markets are not necessarily functional upon exchange in the substantive approach, unless they are fitted in a market system. The ports of trade, gift trade, and administered trade usually fall outside the market system.

Similarly, only one of the money uses coincides with exchange. The rest of the uses analyzed by Polanyi – payment use, standard, ideal unit, operational device – do not necessarily tally with the market, being the typical features of the redistributive integrative form of the economy. The market, Polanyi sums up, is not so old a phenomenon, as are trade and money, and though it may crop up in history, it only integrates into a market system in exceptional cases.

While the former book contained an implicit debate with Hayek and Burnham, this one was challenged by *Economy and Society*, the book of Parsons and Smelser, which sought to integrate economic and social theory and find an alternative explanation about the place of economy in society (Parsons and Smelser, 1957[1956]).

Polanyi's Influence

Polanyi's views were deeply influenced by the writings of Bücher, Weber, Malinowski, Thurnwald, and others (Polanyi, 1977) and Polanyi filtered these influences conveying them to new waves of social research. His ideas were discussed in several volumes, selections, and bibliographies (Stanfield, 1986; Polanyi-Levitt,

1990; Mendell and Salée, 1991; McRobbie and Polanyi-Levitt, 2000; Bugra and Agartan, 2007; Harvey et al., 2007; Hann and Hart, 2009; Dale, 2010). Substantivism and Polanyi appear to be integrated in the history of sociology and anthropology (Hindess, 1977; Smelser and Swedberg, 2005; Beckert and Zafirovski, 2006; Trigilia, 2002[1998]; Radaev, 1997; Gudeman, 2001; Carrier, 2005).

The *Trade and Market in the Early Empires* volume, as well as the posthumous works edited mainly by his disciples (Polanyi, 1966, 1977; Dalton, 1968) and the disputes coming to a head in economic anthropology suggest that a school was evolving around Polanyi. In economic history, Douglass C. North (1977) assessed Polanyi's influence in basically appreciative terms, though criticizing his market interpretation. Polanyi also influenced modern researches centering on the interrelation between state and economy (Block and Evans, 2005; Dobbin, 2004; Fligstein, 2001) as well as studies of socialist economy and its disintegration (Szelényi and Kostello, 1998; Nee, 1989).

According to an evaluation, in spite of his marginal academic position, Polanyi was one of the most influential thinkers of the twentieth century. As far as the sociological analysis of the economy is concerned, this statement might be proved. Polanyi's concept of embeddedness became a point of reference for new economic sociology, although not without controversies (Granovetter, 1992[1985]; Portes, 2010). Embeddedness in the Polanyian sense means subordination of the market to social institutions and interwoven economic, social, and cultural micromotives of individuals. Some representatives of new economic sociology put more emphasis on mesolevel interpretation of embeddedness, that is on relational and structural network position of economic actors (Granovetter, 1990; Uzzi, 2005[1996]). Polanyi referred mostly to historical societies in the analysis of social and cultural embeddedness of economic action. New economic sociologists study how contemporary economic institutions are culturally and socially shaped, or how formal economic motives infiltrate noneconomic life domains and vice versa (DiMaggio, 2002; Zelizer, 2011).

Police: A Sociology of Knowledge Approach

Peter K Manning, College of Criminal Justice, Northeastern University, Boston, MA, USA

Abstract

The sociology of the police concerns the study of the institution of policing, its structure, function, and evolution. This focus requires a sociology of knowledge, a framework that highlights how social factors shape current knowledge of police. The concept of police is a contested one and often assumed without definition. Its functions are associated with governance in general and the executive function in particular. The public policing form assembled by Robert Peel, a visible, reactive force, is an assumed paradigm for much police research, but it is one of several types of policing, and contrasts with high policing concerned with national security. Internationally, broad types or 'families' of policing have emerged as a result of colonialism. Four specific types of police are common in Western democracies: private policing, pubic policing, hybrid policing, and outsourcing or paying organizations to carry out functions previously restricted to police agencies. Metaphors for studying policing, such as dramaturgy, the policing web, and nodal policing, highlight selected features of the policing function. Many external factors shape policing and the future role and function of the police, given new forms of crime, is unpredictable.

The sociology of the police concerns the study of the institution of policing, its structure, function, and development. This perspective implies a sociology of knowledge, that is, how social interests and ideologies shape the sociological study of police. The independent analytic and theoretically grounded study of the police is in competition with a sociology for the police, a response to the practical-occupationally dictated concerns of police command. These two quite different foci lead to different research topics, findings, and definitions of the central topics of interest. The *concept* of police itself is contested, or more specifically, an ambiguous one, as it functions as an institution of governance, an extension of the executive branch. It is generally seen as managing formal social control within the context of the nation-state, and its evolution is related, therefore to social differentiation of functions, legitimate authority, and the emergence of a distinctive mandate.

Although many forms of formal policing exist and are embedded in culturally and legally defined sociolegal systems (Manning, 2010: p. 25), most of the present systematic research concerns policing in common law and continental systems, and the work of police engaged in everyday functions rather than in specific state security functions. It is well to remember that policing had a general function before the late eighteenth century as that which maintained the health or integrity of the body politic, and that the evolution of the concept must be traced through the innovations of the gendarmerie, of policing by Louis XIV and Napoleon. In this context, 'policing' was a combination of national economic interests, national and local security, and represented in time by distinctive organizations (Chapman, 1970; Emsley, 1994).

What is generally considered now the sociology of the police in the Anglo-American world is rather parochial and is traced to the founding of the Dublin City Police in 1786, and to later innovations associated with Robert Peel as Secretary for Ireland and later as Home Secretary. The London-based police of Peel, a response to complex societal changes, was an unarmed, visible, reactive officer standing symbolically between the people and the government. This imaginative and successful move set a paradigm for what is thought of as 'police.' It is only one sort of formalized policing, detached to some degree from national security and order maintenance. This 'Peel paradigm' absent in the armed semisecret riot police was adopted peacefully in counties throughout England by 1855, peacefully in the United States, Canada, and the Antipodes, and imposed by conquest in British colonies. Perhaps the most significant consequence of the diffusion of Peel's concept in time was a political commitment to varieties of localized, somewhat culturally sensitive, control over policing. This was not the case of course in Colonial nations and in non-English-speaking nations. Perhaps inevitably, then, the scope of 'police' and a sociology of the police shrank metaphorically and became synonymous with the study of public, legitimate, state-sponsored agencies that operated within a specified territory and sociolegal political system. Police, found in anomalous circumstances, exceptions to this tacit sketch, such as the gendarmerie, colonial police, police in conquered territories, secret and national-security police, police in authoritarian systems, and police in 'settler states' (Weitzer, 1990, 1995), have not been as extensively studied. The combination of scholarly interest, governmental funding, and the growth of cities in democratic societies led to an interest in and research about public police shortly after World War II. A series of important early studies in the 1960s and 1970s set the tone and focus of the research.

Scholarship

The development of scholarship on the public police in English has been well summarized (Reiner, 2010). But this work, broadly based and concerning police functions, by and large has assumed a well-ordered democratic state with sufficient resources, legitimacy, and a compliant citizenry. These assumptions have obscured 'deeper' questions of policing such as the loyalty of police organizations and their members to the state, their roles in revolution and a *coup de grace*, and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.32107-9

their ideological commitments. They are armed and dangerous; where do their loyalties lie in a crisis? These questions, however, play an insignificant role in the current literature. Studies in the last 50 years or so, published in English with some exceptions, describe (1) socialization to the role; (2) functions of patrol officers and investigators, and lower participants rather than middle management or top command; (3) strategies of policing such as community policing or tactical variations such as 'crack downs' on high crime areas; (4) the organizational and occupational culture of the police; (5) variation in attitudes within the occupation based on race or gender; (6) accountability, corruption, and violence; and (7) the impacts of technology on police practice. There are very few studies of police unions, decision- and policy-making at the top, the internal politics of succession to command positions, or indeed the internal politics of the organization: who gets what, when, and where? There is very little understanding of the current dynamics, emotions, and politics within large urban departments. Whether there is indeed a systematic theory of the police is debatable.

Definition of Police as an Organization

As noted above, the growth of the sociology of police has taken place without much debate over the central yet contested definition of police and policing. If the police as an organization is to be broadly understood, then it must include private as well as public police and include the secret surveillance, tracking, and intelligence gathering that is an essential part of national security. Policing has a mandate, a tacit contract between the public and the police that sets out the boundaries of the actions, and denies these functions to others. Ironically, police are permitted to act outside the law in the pursuit of their obligations (Manning, 1977). Consider this definition of police in modern nation-states with common law or civil law traditions:

> The police, constituted of many diverse agencies, are authoritatively coordinated, legitimate organizations. They stand ready to apply force up to and including fatal force in legally defined territories. They seek to sustain politically defined order and ordering via tracking, surveillance, and arrest. As such, they require compliance to command from lower participants and citizens. Given their wide mandate, they have the ability to proceed by exception.

As discussed below, this definition may require reformulation as Asian forms of policing become better known and researched and the scope of police studies expands. The above definition is an organizationally based definition, which contains a number of ambiguous features, namely, the ambiguity of 'order' and 'ordering,' which cannot be defined in the absence of a sociolegal context, and the capacity for violence. It is thus a formal and normative definition that begs the question of police function. Bittner (1990: p. 131) eschews the normative view, and argues for a means-focus: "The role of police is best seen as a mechanism for the distribution of non-negotiable force employed in accordance with the dictates of an intuitive grasp of situational exigencies." These exigencies, in turn, are best determined by the here and now assessment of the officer. The above definition does include a matter that is implicit in the Bittner definition: the compliance of a pacified citizenry. This trust and related compliance is the source of the police mandate in modern states (Manning, 1977). The framing of the function of modern policing requires a distinction between law and other social norms and values and a *code* or interpretative context into which conflicts are entered. As Bittner (1970: p. 40) points out, the nature of intervention by modern police is not determined by the natural notion of solution that arises from citizens, but lies in the practices of the police in their management of the conflict. This interpretative code is not law, but rather the framing of the case so as to be entered into the legal system. The extension of this formulation is that Bittner focuses on the means, and the idea that, although force is the cornerstone of his idea, police violence is left undefined by the courts and (p. 34): "… police activities cannot be brought fully under the rule of law." Their independence of the courts, spelled out in detail in Bittner (pp. 22–35), facilitates and validates their intuitive actions. They are in effect permitted to act and account for their actions and decisions later. This formulation leads to the rather ironic conclusion that policing's rationality, since it has no known ends, is the rationality of the moment, and this deciding rarely lands in court or comes under significant judicial scrutiny. (Alternatively, one could argue following Jobard (2013) that they remain an instance of organized irrationality in the modern, rapidly rationalizing world. Furthermore, one might argue that their situated actions, because they do not and cannot draw on any fixed rules, combine ignorance and irrationality and are a form of performative magic. The idea that police draw on magic, or are magicians, is not flattery, but is derived from Durkheim's (1961: pp. 58–60) distinction between practitioners of sacred arts, who believe in what they are doing and know why are they acting as they are, and magicians, practitioners do not believe in the tacit premises that govern their actions. They aim to deceive.) This is one facet of the phrase 'proceed by exception' because no precise a priori limit can be set upon their actions. As the above definition states, for the democratic police to manage a pacified audience, they must be able to draw on their dramaturgical powers, the ability to draw on symbols and imagery, and carry out persuasive performances. They are naturally dramatic, and designed historically to produce trust.

Core versus Fringe Imagery

Let us consider another aspect of the sociology of police: the core versus the fringe imagery of police. Imagery is the ways in which the police present themselves – dramatize their actions and intentions – and how they are seen. The core imagery in Western industrialized societies is the visible, uniformed, reactive, service-oriented patrol officer, while the fringe functions, less visible and rarely considered or written about, are carried out by specialized paramilitary units, riot-control, surveillance and tracking functions, often now associated with antiterrorist activities, and units devoted to 'high

policing' (Brodeur, 2010). Nonuniformed officers are also engaged in such activities from time to time. This blindness to covert and less-than-visible activities has meant that a disproportionate amount of research in the sociology of police has been devoted to the activities and occupational culture of the uniformed officer, and relatively little to investigators, top command, and specialized units (Marks, 2005).

Historical Modes of Formal Policing: Centers and Peripheries

Most people in the world live under political arrangements that developed outside the historical core of the capitalist world system. Scholars in a number of disciplines have contributed accounts of histories and practices of policing in the 'alternative modernities' endemic to postcolonial or developmental environments. This diverse literature has recently begun to coalesce around the relativism of cultural anthropology into a sort of critical theoretical counterpoint in dialogue with the mainstream sociology of police (Garriott, 2013; Jauregui, 2013). Colonized societies saw anthropologists and police arrive together, as partners in the colonial system of control. Decolonization then forced contemporary anthropology to reevaluate the ways its inherited archives of 'cultural' information were implicitly structured by the practical concerns of the colonial officers who created them (Pels, 1997). Critical studies of the classification of populations in British South Asia (Cohn, 1987), Dutch Indonesia (Stoler, 2009), and elsewhere have illuminated some of the many ways cultural knowledge has historically functioned as a police technique. The contemporary anthropological study of policing takes this lesson to heart, examining policing as a field of knowledge/power in which a variety of institutions operate as means to diverse ends, structured by a plurality of hoped-for ideals of modern peace and/or prosperity (Comaroff and Comaroff, 2006).

Globally comparative discussions of policing arrangements are generally organized under historical and regional themes. Historically, there seems to exist a roughly tripartite typology of institutional 'families,' depending on whether a given policing system is derived from Anglo-American, Continental, or Soviet roots. Studies of policing in the former British Empire (Anderson and Killingray, 1992; Sinclair, 2006), e.g., show how the common law ideal can be differentially taken up as an element in a local 'policing vernacular' (Hornberger, 2011). Latin American policing, by contrast, is largely derived from the Civil Law tradition (Uildriks, 2009). Ethnographies of contemporary Latin American policing have focused on the 'disjunctive' qualities that arise where centralized policing systems serve to maintain radical economic inequalities (Caldeira, 2001). East Asian policing, finally, grows out of the Japan's nineteenth-century appropriation of French and German legal and administrative institutions (Martin, 2014). Subsequent to its 1949 revolution, China developed a totalitarian system that projected police power deep into the minutiae of everyday life, enforcing socialist order onto things ranging from the way words could be written to the number of children that could be born. China's subsequent success translating this authoritarian system into the developmental mechanism it has used to become a capitalist world power makes contemporary Chinese policing something of a *sui generis* formation, which is only beginning to be critically studied (Cao et al., 2014).

Types of Policing

Policing, as noted in the above formal definition, includes private as well as diverse forms of public policing, and as such, contrasts with *informal policing* or perhaps 'self-appointed or nominated policing,' which includes ad hoc policing, posses, militias, vigilante groups, and other informal, part-time policing individually or collectively that is carried out without uniform, pay, and specific conditions of employment. These informal police officers cannot be fired and thus their accountability is dubious. There are also 'minders' of public order who in the course of their duties sustain orderly activities, e.g., taxi drivers; traffic and parking attendants; bus, train, and subway drivers; emergency medical services and emergency personal; and members of the fire service. Thus, a sociology of policing differs from a sociology of the (formal) police. The range of functions carried out by the public police is diverse and complex. More is known about the workings of formal public police than about other forms.

Within the industrialized world, examination of formal policing reveals many types of policing with varying *mandates*, or legitimate validation of their claims to control the proper attitude toward the work, their rhetorical and resource-allocation strategies, and tactics and accompanying themes or *dramatic emphases* in their rhetoric, uniforms, and actions. In many ways, modern public police emphasize a theme of responsiveness, service, and crime control. They are in competition for legitimacy with other types of and of course informal social control. Here are some types of formal policing, their interests, and themes:

- *Private policing* – paid for actions in regard to maintaining and or expanding private interests. Usually connected to policing given territories. Policing with private interests as the mandate only marginally, if at all, serves the public welfare, even when policing quasi-public property. The functions carried out by private police are those connected with not only sustaining order in quasi-public spaces, but also in all those areas in which control of a citizenry is dubious. The theme here is prevention.
- *Policing carrying out traditionally public police functions* – using public funds to pay for agents to carry out functions connected the public good, e.g., traffic tickets, order maintenance; regulation that does not entail arrest in excess of 'everyday' citizen powers. This is also called 'outsourcing' on the grounds that it reduces costs and functions by contracting. Such policing functions have a mandate in the sense that they are licensed, legitimate, and have territorial limitations. They draw also on the mandate of public police by simulating their uniforms, interactional style, the decoration of their vehicles, and symbols. In the United States, they carry visible weapons. They may or may not include some arrest powers in private spaces for trespassing. The theme is protecting boundaries.

- *Hybrid policing* – varieties of policing, i.e., noticing, responding to, and perhaps sanctioning behavior with a quasi-public mandate. This sort of policing is now included in the 'police family.' The confusion in regard to legitimacy comes in that these functions can be carried out by police employed privately, police employed and paid by the public, or some amalgam of these. This can also include third-party policing and varieties of the police web. The theme here is service.
- *Public police* – the police organization includes warranted officers, those with arrest powers, and those who are not warranted or sworn. These 'civilians' can make up as much as 50% of the organization's employees. In addition, the organization can include reserve constables, cadets, and part-time officers. The organizational culture includes more than the segmented occupational culture of the police. The theme here is responsiveness and service.

In addition, the status of federal agents, the military and military police, and military investigative services in the United States, Australia, and Canada, is ambiguous. They carry out many functions that are unrelated to national security, overlap or compete with local jurisdictions, and operate primarily within federal laws and courts. There are also highly specialized police forces in the Anglo-American world with quite precise and limited mandates, which mean that they are not in competition with the above-listed types, e.g., British Railway Police; Amtrak (US railroad) police, and the police of an American rural development project, the Tennessee Valley Authority.

Policing and Metaphors

To study modern policing requires more than the study of police organization or even policing; it requires metaphoric work. The sociology of police rests on metaphor: a way of seeing something in terms of something else. If we conceive of the police as 'law enforcement,' we reduce them to a mere part of their whole; if we call them a 'business,' or an agency providing human services, we are treating the whole and denying many of the parts. The expansion of vision that has taken place in the last 20 years in the sociology of police, a result of transnational communication, migration, and travel, as well as transnational policing, now requires an understanding of how types of policing rather than merely public police are to be seen and seen to be in competition or conflict with each other. Brodeur (2010) has suggested the metaphor of a *policing web* or assemblage that connects loosely those agencies that police in some fashion. These organizations are a collection that is to some degree in conflict, in competitive, and/or conflict mode over time and across incidents. Think of this assemblage as a web: the strands are unequal in strength; the number of their connections varies, and the content, the communications exchanged, vary in density and frequency, e.g., information about crime, disorder, villains, and disasters. This shifts attention away from myopic focus on public police, draws attention to multiple and competing policing functions, and suggests the overlap of surveillance and control in which citizens are embedded. The web concept is, however, focused on agencies and organizations, not on interdigitated functions, and Brodeur's position is that the public police are and must remain the center of authority primacy of resources and collective obligations. A parallel and equally fascinating *trompe d'œil* is Shearing's notion of *nodal policing* (2005), which begins with charting functional capacities, technologies, mentalities, or socially grounded perceptions, and institutional arrangements. These clusters of functions are arrayed in some sense around social security or a collective sense of well-being. They do not stand as organizations but as nodes of function. These are seen as contingent arrangements for addressing emerging problems, rather than conventionally mandated responses to anomalies. In some sense, the idea is an analogue to the open market or invisible hand notion of organizing responses. There is an element of spontaneity about such responses. The public police are partners in this enterprise of security maintenance, and seen as cooperative partners in problem solving. These metaphoric moves open up new vistas and new avenues in the sociology of police.

The Role of External Factors

In the course of the development of the interdisciplinary field of police studies, the focus has been on the police organization as a dramaturgical actor within a field, the activities of officers, both investigators and uniformed officers, or the occupational culture and subcultures. In the last 20 years, the focus has been on tactics, crime control efforts, and efforts to measure and prevent crime. Surprisingly, the role of the organizational, political, and economic environment has been described in the abstract by economists and political scientists, but few empirical studies demonstrate how such external factors actually pattern policing practices such as arrest and enforcement targets. Developments in the last 30 years, inexpensive communication, travel, migration and immigration, the rise of terrorism and antiterrorism, global commerce, and international, transnational, and metanational policing (Bowling, 2010), have also widened the vision of scholars. The future problems of technocrime, international organized crime, and terrorism influence the police differently in developed nations. How and to what extent these influences will shape the police mandate, strategies, and tactics is yet to be determined.

Methods and Problematics

The study of police is problematic because access is difficult, the police are secretive and often suspicious of research and researchers, the work is diverse and spread out ecologically, and police data require context to interpret. They require translation and back translation (they are gathered in a context that is not the same as a research context). The early research was ethnographic and fieldwork based, and later studies expanded to include other police-gathered-data (officially recorded crime), interviews, questionnaires, and police records. Attention shifted in the 1980s to community policing and attitude data gathered from the public. Recent attention has been on crime reduction by manipulation of police presence and formal designs to measure the impact of tactics on the reduction of

crime and disorder. An abiding concern of researchers has been normative, concerned with corruption, excessive use of force, accountability, race profiling, gender and minority mistreatment both within the organization and outside it, and the quality of police–citizen interactions. Of late, reducing officially recorded crime has been a research focus. The impacts of new electronic technologies has not been closely examined, even as police develop Web sites and interactive blogs accessible to the public; employ social media, such as Facebook and Twitter; and maintain Web sites. While use of cell phones in the past was considered a breach of security as well as a violation of the chain of command, they are now considered part of the everyday equipment of all officers (it is likely now that most officers above the rank of sergeant carry at least two smart phones, one their own and one a departmentally issued phone).

The Future of the Sociology of Police

The future of the sociology of the police cannot be predicted. The sociological frames of reference within which police and policing are cast; the practitioners' interests, which bear an abiding influence on the research; and the inevitable fads and fashions in social science all will shape intellectual problems and research methods. Global issues such as the ongoing turmoil in the Middle East, global warming and related changes in the climate, bodies of water, and natural disasters, as they are seen to be in the ambit of the police, will shape the coming century of research. A corollary of the rise of democratic policing and governance is the resistance of the powerless in the form of terrorism and the response of antiterrorism tactics, paramilitary units, and increased surveillance. The issues that may arise are questions of democratic policing as it is associated with emerging nation-states, changes in the political economy of developing nations, and the growing importance of human rights.

Abstract

Police as a formal institution of social control, organized within the framework of the nation state, emerged during the course of the eighteenth and nineteenth centuries. Although some issues of police and policing had been studied by the classic authors of sociology, it became a subject of genuine sociological study only after World War II. Early research was focused on empirical studies of police organizations and the actual work of police officers, coupled with theorizing. As a new and special terrain of research, sociology of police was at its height in the late 1960s and the 1970s among Anglo-American scholars. From then on a growing body of literature dealt with judicial, organizational, occupational, and political aspects of police work, however rarely under an explicit label of 'sociology of police.' Today, police is a topic for different academic disciplines, among them sociology.

Introduction

The *sociology of police* as a specialized area of study can be defined as the empirical and theoretical analysis of those institutions charged with the investigation and prevention of crime and the maintenance of public safety and order. Such organizations are usually, but not exclusively established by state governments. Such a subdiscipline is necessarily interdisciplinary, and embraces the systematic enquiry about the role of police in modern societies, the general characteristics of policing bodies and their relation to other institutions, the institutional development and internal structure of police forces, the collective and individual behavior of their members, and the interactions or relations of those agencies with individuals, different social groups, institutions, and the general public.

Police as a Matter of Sociological Concern

Both police and sociology are offsprings of the Enlightenment and the Industrial Revolution. Although the contours of both as we understand them today became obvious only in the nineteenth century – the former as a new formal institutionalization of social control, the latter as a new academic discipline – there is a line of discourse which can be traced back to ancient times, when Roman emperors struggled to get or keep their rule by using armed forces and when philosophers reasoned about the art of best governance. Despite the fact that the contemporary notions of 'police' and 'sociology' were not yet understood as such then, the reasoning about the necessity of establishing and maintaining a public force to control crime and to ensure public order – and the critical discussion of its actual appearance – is as old as the discourse on the *res publica*.

Later on, the issue of police was embedded into the broader philosophical topic of the state and government by early classic sociologists and social philosophers. For example, police were discussed mainly as an instrument for the sovereign's power to govern. Max Weber's often quoted notion that the state is that human community that successfully claims a monopoly of legitimate use of force within a certain territory still prevails within academic reflections on the police, either explicitly or implicitly (Bittner, 1991).

With the growing urbanization of the countries in industrial and technological transition, there was also an increasing body of literature on police matters from a pragmatic perspective in the first half of the twentieth century. Yet it took some time for the police to become an explicit and original matter in sociological thought and empirical inquiry, primarily in English-speaking countries. Such a change was largely due to a new era in the mid-twentieth century of the sort of civil transition that heralded creation of the police in the nineteenth century, such as race riots.

Determining the Subject

At first glance and seen from the surface, it seems rather trivial to determine who and what constitutes 'the police.' One would expect that the police as a public institution is represented by sworn officers, i.e., representatives of the state and its government, who are trained professionals uniquely invested with certain powers like the authority to search or arrest a person. Usually this 'apparent' kind of police will appear in public as officers on the beat, a crew in a patrol car, behind a desk in a police station, or as plainclothes detectives doing investigations in the field. This is the common and popular image (in the Western world) of what police actually are, transmitted by the media and supported by occasional ordinary encounters. From time to time this picture is widened by the appearance of riot police in full gear, underlining the state's authorization and capability of using legitimately physical force against disobedient citizens or rioting crowds.

When one looks again at who and what constitutes police, the semblance becomes more complicated. On the level of involved actors, it becomes apparent that a good portion of the workforce employed by the police consists of civilian staff, like secretaries or the clerks in the forensic laboratories; some sworn officers, such as staff who are responsible for conducting statistical analysis of criminal incidents or running a computer

program for matching data, are rarely out in the field, while certain field officers, like undercover agents or specialists in charge of surveillance of telecommunication, often do not act openly as police. Furthermore, there are other state agents who, having similar powers of investigation or intervention, perform certain functions of policing, but are not seen or labeled as 'police.' One might think here of custom officers, public health inspectors, water rights investigators, or prison guards.

As professionals trained to use state-sanctioned – and sometimes lethal – force, the police are unique. But on the level of routine work processes, this distinguishing feature is a rather rare event compared to the overall picture of police duties. Instead, research has shown that a considerable part of the modern police workload is not at all focused on crime control and investigation of criminal cases, but consists of responding to general emergency calls, mediating conflicts, regulating motor vehicle traffic, and communication with other institutions or agencies like social services, insurance companies, etc. Even the popular notion that an officer's shift consists of 7 h of absolute boredom and an hour of sheer terror exaggerates the reality.

Although it might be clear from a commonsense point of view what 'police' actually are, the subject in question gets more diverse the more we see it from a perspective of a peculiar organized social activity rather than as a matter of institutionalism. Thus, a true 'sociology of policing' would cover a wider area and embrace more organizations than initial 'police studies.' To wit, others appear in a policelike guise, but they are clearly not sworn officers (at least lacking their full powers): city wardens, commercial guards and patrols, hired investigators, vigilante organizations like the 'Guardian Angels,' bodyguards, stewards in a football stadium, or bouncers. This category might also include the pattern of civilianization among police agencies, where nonsworn officers are sent on routine reporting calls, such as cold burglaries.

It should not be overlooked that police as a subject of sociological interest is linked in many ways with other social systems, all of them carrying their own, often overlapping, bodies of literature. As an instrument of executive governance 'the police' can be seen as a segment of the *sociology of the state*. On the other hand, its quality of being an important part of the criminal justice system and its more or less explicit legal bindings makes it a component of the *sociology of law*, as Donald Black (1980) has argued. Finally, on the level of empirical studies, there are clear ties to the field of *organizational sociology*, as John Crank (2003) has suggested.

Changes in Focus and Emphasis

Although some academic work on the police can be traced back to the 1950s and earlier, the first surge of sociological studies of police work occurred during the aftermath of the increasing social and political changes that affected most countries of the Western world from the early 1960s on. In a time when social and political conflicts were brought onto the streets, and rising concerns about crime and disorder became a public issue, 'the police became increasingly visible, controversial and politicized in response to these tensions and pressures' (Reiner, 2000, p. 210).

According to Cain (1979), five types of studies, following a rough chronological sequence in the shift of areas of interest, can be identified for this period: (1) a law-related concern with civil rights when confronted with police powers and discretion; (2) examinations of the police organization by participant observations (Skolnick, 1966; Manning, 1977 are well-known examples); (3) studies of the roles that the police take in the social construction of deviants and the fabricating of public images of deviance; (4) analysis of the interactions and relationships of the police with the social environments they are working in; and (5) studies questioning the political contexts, presumptions, and consequences of police activities. It can be said that all these topics overlap in a way and have persisted during the proceeding decades.

There are two important points to note. First, that most of the aforementioned research was overwhelmingly conducted in the USA and the UK. Second, the main characteristics of this work, coming out of universities, private organizations such as the Police Foundation, and government agencies such as the Home Office, were motivated by a concern with issues of the use of police discretion and generally tended to be critical of the police. For example, the famous Kansas City Preventive Patrol experiment aimed to understand how police discretionary behavior (in terms of random patrol) impacted crime and fear of crime, and found, ultimately, that it did not necessarily have such an impact. This evaluation interest was grounded in the awareness that police did not always use their discretion as expected, or in moral ways, brought about by the aftermath of the 1960 race riots.

The policing research that was conducted by private think tanks such as the Police Foundation and the Police Executive Research Forum, and government agencies like the Bureau of Justice and the Home Office, tended (and tend) to focus on questions of good practice and evaluation of reform measures, and are generated under policy and managerialist perspectives (Reiner, 2000). And so we not only have the Kansas City Preventive Patrol Experiment, we have a general research agenda of *what works*, or, as the buzzword *par excellence* of the twenty-first century would put it, *evidence-based practices*. This followed a general trend in governance, but ultimately complicated the *role* of the police. As it became more apparent, from research, that police by themselves could do little to impact crime, their relationship to government, society, and community became increasingly complex.

Current Theory and Research

There has been precious little theorizing in policing over the last 30 years. The bulk of policing scholarship continues to draw on the 'classics' of policing theory, such as the works of Black (1980), Van Maanen (1974), Manning (1978), Wilson (1968), Jackson (1989), and Skolnick (1966). Still, there is a small group of theorists who have expanded policing theory, including Kane (2002), Klinger (1997), Bernard and Engel (2001), and Crank and Langworthy (1992). For the most part, these theories are quasifunctionalist with a Marxist bent, and rely heavily on institutional and psychological theories.

A number of trends in current policing research can be discerned, although much of it is carry-over from previous

decades. For example, we are still interested in aspects like recruitment and education, gender and minority issues, the role of unions and professionalism and specialization, and questions surrounding the use of force, particularly those conducted with electricity devices (e.g., the electroshock weapons for neuromuscular incapacitation manufactured by TASER). The question at stake here is not just what police are actually doing, but is it effective and why or why not. An enormous amount of scholarly energy and government monies have been expended in the last two decades trying to even understand what is meant by the term 'effective' when it comes to the police. This debate continues. Nevertheless, a 'what works' and 'evidence-based' research agenda largely dominates policing scholarship today, with or without theory backing it (Cooper and Worrall, 2012).

A good portion of police research literature is still concerned with issues of internal, as well as external, control mechanisms of individual and institutional police behavior. In this respect, the institutional autonomy of the police in the face of the government and the judiciary is one side of the question, while the control of the behavior of individual officers is another (Marx, 1988). The work of Samuel Walker (see especially 2005) and the movement in the USA and abroad to implement citizen oversight of police continue to be relevant.

Comparative Police Research

It is still the case that the bulk of police studies which are relevant for the sociology of police in one way or the other is produced in English-speaking countries, with the USA in a clear lead. This might be seen as the reason why, on an international level, the discourse on police and policing issues mainly reflects these countries. For example, debates on 'community policing' or 'zero-tolerance strategies' originate from the development of police policies in the USA. But as matters of cross-border and international police cooperation have become more important since the early 1990s, there is a growing interest in comparative perspectives (Brodeur, 1995; Findlay and Zvekic, 1993). This has especially been the case as other non-Anglo-American and even non-European countries have begun to take policing scholarship seriously – such as Belgium and the Netherlands, and South Korea. Indeed, it has only been very recently that the European Society of Criminology has formally adopted a police working group, the creation of which was pushed to a large degree by Scottish and Belgium scholars.

The contemporary sociology of police and policing has to take two aspects into account. First, there are quite a lot of significant differences in how police institutions are organized and how policing methods are actually achieved among different countries. This is mainly due to diverse national historical backgrounds. The diversity lies particularly in the arrangements of the police system that are influenced by legal, political, and occupational cultures (Busch et al., 1985; Monjardet, 1996), as well as the distinction between civil and common law systems, to say nothing of the added complication of federalism versus centralization of government. The other aspect is that when it comes to the level of policing (i.e., how police work is actually achieved and what kind of resources and strategies are used), some striking similarities and convergences can be noted. There seems to be an increasing transfer of issues in the international police discourse.

Increasingly, matters of police management and evaluation are discussed, especially those that are connected with institutional police reforms in the UK. Modernization and technology seems to have been an enduring issue in police reform since the 1970s throughout the globe.

Methodological Issues

There have always been some difficulties for police organizations granting outsiders access to internal functional mechanisms because it carries the risk of 'occupational secrets' becoming subjects of public discussion. This has become somewhat easier as police have come to recognize the importance and usefulness of evaluation research. Generally, from a methodological point of view, three points deserve attention. First, police studies that are relevant for sociological interests can be roughly divided into basic and applied science. In basic science, the police scholar is more concerned with theoretical issues and less concerned with practical issues; to oversimplify the matter, the opposite might be said to describe applied science. Of course, both applied and basic police science make use of theory and discuss practical implications. Nevertheless, contemporary policing research is often presented along these theoretical or atheoretical lines (cf Cooper and Worrall, 2012).

Another issue considers who initiates and/or carries out the research in question. It might make a difference for methodological approaches, as well as for the broadness of the theoretical perspective, if studies are done by researchers coming from police or other government institutions or if they are carried out by university institutes. When police behavior is observed from the outside – that is, by university researchers – especially in respect to its effects on citizens, it is a matter of external description and analysis. When researchers work from within an agency – or in collaboration with an agency – the internal perspective of the field actors can also be reflected in the research on police. Both have value and pitfalls that must be taken into account when evaluating any policing study.

Furthermore, there is a clear difference between research *for* and research *about* the police. Usually the former tends to be preoccupied with practical issues or management problems that need a quicker turn-around than rigorous social science can provide. Although there quite often exist interesting sociological aspects within these perspectives, a genuine sociology of police and policing is coupled with research *about* the police (i.e., its meaning in relation to the law, the state, or as a social response to deviance in general). To the extent to which research is *for* the police it may depart from the usual methodological considerations of the sociological imagination.

Finally, the term 'police' might be a category that is too broad when it comes to empirical analysis and theoretical conclusions. Not only do national police systems embrace a variety of more or less specialized forces, with specific and sometimes unique ways of division of labor among units, but police organizations also refer to very different geographical ranges of jurisdiction. This situation becomes more complicated when nationally focused studies are compared on an

international level: for a full comprehension of the differences and convergences, national particulars have to be taken into account.

Future Directions of Theory and Research

As any perusal of advertisements for criminology and criminal justice faculty positions will reveal, policing scholars – and their scholarship – are in high demand. It is perhaps ironic that many of the research threads that existed in the 1990s and early 2000s, or even earlier, are still being pursued. For example, scholars continue to explore the privatization and militarization of the police, their impact on not only crime but on disorder, as well as police officer characteristics and their effect on discretion, including officer satisfaction, motivation, race, gender, etc. Such research questions are hardly new in policing scholarship; what is new is a very strict positivist approach to these subjects. Prior research, following Weber's lead, combined empirical methodologies with an explication of data often more at home in the humanities than the scientific method. For the last decade, and the foreseeable future, policing research seems intently focused on more exact specifications that can be 'objectively' measured.

This *uber*-focus on measurement and outcome has – somewhat ironically given the seeming adoption of strict positivism – led a number of police scholars to either ignore theory altogether or to plug it in post hoc. Some policing research has, however, followed the rules of basic science more closely, either testing or articulating theory. For example, Wilson's (1968) book *Varieties of Police Behavior* continues to guide policing research to a great extent, as does Klinger's (1998) territorial explanation for police behavior.

More prominently, policing theory borrows from mainstream criminology. This pattern is less a matter of the evolution of police science, and more a matter of academic training. Most of the theories in the 1960s and 1970s were based on institutional and systems theory, which reflected the sociological and political science training of their authors. Today, more and more, police scholars come from criminology and criminal justice programs, and this theoretical background dominates their writing. Social learning theory, low self-control, and social disorganization (inter alia) have all been implicated in the last 15 years to explain the behavior of police officers and of the police.

Because policing research is, to a great extent, driven by American research, and because that research is driven, to a great extent, by monies from the government in the form of grants, it is no surprise that the future of policing research is mirroring the future of policing itself. Namely, as police departments began to use problem-oriented and situational crime prevention approaches more regularly, work with community groups, and engage in evaluation research, they concomitantly work more closely with researchers – both in-house and externally. The real questions facing police scholarship for at least the next 20 years should ask how does the scientific method apply to policing? What is the role of technology in this process? And finally, what are the implications of these changes, not only for civil order, but for civil rights as well?

Police Use of Force

Geoffrey P Alpert, University of South Carolina, Columbia, SC, USA; and Griffith University, Brisbane, QLD, Australia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The police have authority to ensure public safety by enforcing laws. Although the core of police work is cooperation, officers are sometimes required to use physical force. The nature and types of force used by the police create a perception of their legitimacy among the citizens they serve. This article discusses the use of force by police and provides a context to understand its use and abuse.

Introduction

In our social world, we rely on the police to protect us and ensure our safety. We provide them with the authority to use force and thereby differentiate them from other civilian employees (see Bittner, 1970). Although the authority to use force is the necessary and defining characteristic of the police, it brings with it exceptional scrutiny and oversight. This article discusses the use of force by the police and helps us understand its contours. We start with a brief understanding of when police use force, turn to the current legal standards that authorize it, provide an explanation of the context of police use of force and what our research findings teach us, and conclude with a conceptual framework to understand why police–citizen encounters result in the use of force.

Although we know the police have the authority to enforce the law and ensure public safety, we do not always know how much force or what type of force is reasonable and when force used by the police is unreasonable and excessive. We must recall Egon Bittner's (1970) clarification more than 40 years ago that while the use of force is at the core of police work, the true skill of an officer is to accomplish the police mission of saving lives and protecting society while avoiding the use of force or using only a minimal level of force as situationally justified. Bittner's explanation holds true today, although officers face more serious threats from citizens than they did in the 1960s and 1970s (see Alpert and Dunham, 2004). Similarly, the actions of the police that might have been reported on the evening news are often seen on YouTube shortly after they occur. Our digital world has increased the speed and flow of information, but the use of excessive force has the same damning effect on society and loss of trust as it did decades ago. Over the years, psychological and technological innovations have helped the police negotiate with suspects and deal with them in ways that reduce the likelihood of using force to control them. Skills including verbal judo, violence reduction, and other useful interpersonal communication techniques have all helped reduce police use of force and the likelihood of suspect resistance and injuries (Police Executive Research Forum, 2012; Prenzler et al., 2013). However, if all else fails, the use of force is the officer's last resort to control a suspect's resistance to a lawful order. Beyond the psychological advancements, less lethal technologies, including oleoresin capsicum (OC spray) and conducted electronic weapons (CEWs), have become very popular in the twenty-first century and an important part of police work.

The use of force by the police plays a critical role in how citizens view them, earning or eroding public trust, and developing or limiting cooperation with citizens to provide information on crimes and criminals. It is human nature to respond negatively to misconduct, or the rare and shocking abuses of power rather than positively to the routine, appropriate, and numerous thoughtful acts that are performed most frequently by the police. Citizens want to have positive attitudes toward the police but it is perception rather than reality that often paints the picture that impacts the public's views and responses to the police. Managing that perception can be impacted greatly by understanding why, how, when, and in what situations police use force, as well as the level and type of force that is applied. The true picture of police use of force is not as interesting as the one painted by the abuses that create attention and publicity. Police use of force is a rare event, estimated to occur in approximately 1–2% of all encounters between the police and the public, and even the majority of those uses of force are minor and do not result in significant injuries (Walker and Katz, 2013). However, the percentage of encounters in which force is used will fluctuate depending on how force is measured and how encounters with citizens are recorded. In today's world, many police agencies define force only as actions beyond verbal orders, handcuffing, pat-downs, and 'come-along' holds. They also do not record all police–citizen encounters but limit reporting to the most serious ones, which are differentially defined. Although the number and percentage of incidents in which force is used may vary by accounting procedures, the impact of each remains a critical moment for police–public relations. Most use of force applications are in response to citizens' aggressive or physical refusals to obey orders, but determining when each use of force crosses the line from reasonable to excessive, from appropriate conduct to misconduct, is a difficult determination.

Determining Excessive Force

As important as, and more problematic than, determining the nature and extent of police use of force, is the determination of the force as reasonable or excessive. The standard for this distinction is set by the courts, and interpreted by agency policies, procedures, training, and supervision. Police

departments rely on the standards established by dicta from the US Supreme Court in its opinion, *Graham v. Connor*, 490 US 386 (1989). In the *Graham* case, the Court provides the general framework for assessing whether a particular use of force is legal under the Fourth Amendment. This, as most general standards found in Fourth Amendment precedent, operates through a balancing test of the nature and quality of the intrusion on the individual's rights against the countervailing governmental interests. The facts of the case are important to help understand the dynamics of the police–citizen encounter. Mr. Graham was suffering from an insulin reaction and went to a store to purchase orange juice. Because of the long lines and Graham's need to get a 'fix,' he quickly exited and headed to a friend's house. A police officer who was observing Mr. Graham's behavior of quickly entering and exiting the store became suspicious and conducted an investigatory stop. The interaction between an officer who formed suspicion based on his observations and a citizen who was suffering from an insulin reaction resulted in misunderstanding, misread cues, physical force, and resistance. The officer's actions gave rise to a use of excessive force claim against the police. In its decision, the US Supreme Court provided guidance to determine the appropriate level of force used by the police. Specifically, the court used a three-question test to measure the reasonableness of a particular use of force:

1. What was the severity of the crime that the officer believed the suspect to have committed or be committing?
2. Did the suspect present an immediate threat to the safety of officers or the public?
3. Was the suspect actively resisting arrest or attempting to escape?

The court provided more direction and declared (at 396): "the calculus of reasonableness must embody allowance for the fact that police officers are often forced to make split-second judgments – in circumstances that are tense, uncertain, and rapidly evolving – about the amount of force that is necessary in a particular situation." The court also stated that the use of force should be measured by what the officer knew at the time, not by the '20/20 vision of hindsight.' In the nearly two decades since the *Graham v. Connor decision*, courts have refined the three-prong test and adopted several additional factors in the formula to determine the objective reasonableness of police use of force. For example, the degree of the threat posed by the suspect based on size, strength, and numbers has become part of the equation. When officers are outnumbered or confronted by particularly powerful suspects, higher levels of force may be justified than when officers are confronted by a lesser threat (see *Sharrar v. Felsing*, 128 F.3d 810 (3rd Cir. 1997)). Courts may also consider the immediate availability of less lethal weapons (*Tom v. Voida*, 963 F.2d 952 (7th Cir. 1992)). The subject's history of mental illness or level of impairment due to alcohol or drugs may also be considered when analyzing the threat posed by the suspect and the response by the police (see *Krueger v. Fuhr*, 991 F.2d 435 (8th Cir.), *cert. denied*, 510 US 946 (1993); *Hunt v. County of Whitman*, 2006 WL 2096068 (E.D. Wash. 2006)). Although the factors may change or be interpreted differently, the language remains the same: an officer may use only that force that is both *reasonable* and *necessary* to make an arrest or apprehend a suspect. Anything more is *excessive force* (*Payne v. Pauley*, 337 F.3d 767 (7th Cir. 2003)). Understanding the legal strictures sets the stage to understand what we know about police use of force.

The Context of Police Use of Force: What We Know

Research has been conducted on police use of force for more than 40 years and the results show important information about the nature and extent of force used by the police as they attempt to control suspects or respond to resistance from them (Alpert and Dunham, 2004; Alpert et al., 2004). The quality and quantity of information on police use of force incidents recognized by researchers and policymakers have increased dramatically in recent years. Findings from this body of research illuminate methodological shortcomings including work conducted from the perspective that use of force events are static, and that the data have focused on the officer's point of view (Alpert and Dunham, 2004). Additionally, the conceptual frameworks used to understand police use of force have not been linked together properly (see National Research Council, 2003).

Despite acknowledged shortcomings, research has provided important information to guide our understanding of police behavior. Most of the social science research on police use of force has been conducted since the 1970s (Garner et al., 2002) and in the largest police departments (Alpert and Dunham, 2004). As Herman Goldstein (1990, 9) informs us, "The police came under enormous pressure in the late 1960s and early 1970s as they were confronted with concern about a rapidly rising crime rate, civil rights demonstrations, racial conflicts, riots, and political protests of the war in Vietnam." This interest in studying the police and their control tactics was basically generated by their linkages to social and political events. These questions and concerns about police behavior led to an increase in federal funding for police research and a corresponding improvement in ways to study them. In other words, the reform and research movements were linked inexorably. Prior to the increase in systematic research, most information on police violence was anecdotal, but helped the reform movement gain traction. According to Garner et al. (2002: p.707):

> The narrative accounts by independent researchers tended to emphasize the researchers' personal interpretations of police work and to highlight alleged and sometimes confirmed incidences of unusual, dramatic, illegal, or inappropriate behavior by officers or civilians. These descriptions and insights provide a valuable basis for generating hypotheses about the nature of force and the situations in which force is used. However, because they have been limited to personal observations of a few officers in a few precincts in a few jurisdictions and have relied on qualitative assessments of single observers, these personal narratives provide an incomplete and potentially inaccurate picture of normal contact between the police and the public.

The recent era of research on police use of force has included traditional social science methods, including analysis of existing police records; surveys of officers, suspects, and members of the public; interviews with officers and suspects; and observations of the police in action. Overall, our knowledge is limited and results are mixed but our concerns are fervent. In some studies,

we learn that police use force more often and at higher levels against members of minority groups than white citizens, while in others there are no differences. The use of force against people with mental deficiencies or under the influence of alcohol or drugs remains an important topic that is difficult to study and understand, and research findings concerning how officers respond to this population are mixed as well. We investigate the use of force in specific areas, especially high-crime and lower socioeconomic areas, because it occurs more frequently in those areas than low-crime, middle-class areas. Generally, we investigate the use of force by officers in the larger departments and try to determine if some of them use force or use higher levels of force more often than other officers, against identifiable groups, or in specific places. We look at the age, gender, ethnicity, and experience of officers; when and where they are working; and the social, political, and economic conditions of their assignments. We look at training and supervision of officers, as well as the policies under which they operate. We consider the age, ethnicity, social class, and criminality of citizens who resist the police and on whom force is used. Although our research goals are appropriate and conventional, our results are mixed and difficult to interpret (National Research Council, 2003). Our concentration of research on people and places is premised on successful social science research strategies, but our results do not provide policymakers with definitive information or 'best practices' to train or guide officers.

Although the empirical findings from our collective research may lack specific policy mandates for managers, there have been advancements in the ways we look at police use of force and how we try to understand it. First, we have learned to consider use of force events as live, high-stress, adrenalin-driven interactive events that must be understood during the beginning, levels of interaction, and end (Alpert and Dunham, 2004). Second, we must consider not only an officer's version of the event, but also any physical evidence such as a video or audio recording of the event, any observation by a witness, and the story told by the suspect. Here we learn that how the story is told becomes critical in its interpretation and understanding (Rojek et al., 2012).

A significant advancement in use of force research is the improvement of research on the interactive model of police–citizen exchanges. We recognize that the goals of a police officer are to define and control a situation, and we agree that a citizen will likely cooperate with the officer unless the citizen believes the officer is going to take action that is contrary to his or her interest. When that occurs, citizens may resist verbally, with and without success. However, if neither actor acquiesces, both officers and citizens can act in ways that frustrate the other, giving rise to a subset of interactions that can escalate the situation until one of the actors resorts to force or physical resistance. Although we have not learned exactly why some people act differently than others, we do know that the goals and objectives of the encounter are different for the police and the citizen. Because the behaviors in a police–citizen encounter are not static but change as the event unfolds, it is necessary to understand more thoroughly how police and citizens respond to cues, other forms of nonverbal behavior, and the actions and reactions of the other actors, including witnesses.

Limited research has been conducted to capture the significance of the interaction sequences of police–citizen encounters. Alpert and Dunham (1997) developed the Force Factor, a measure of the level of police use of force relative to the level of suspect resistance. This interactive approach has been extended not to look at just the highest level of force and resistance but also to investigate how each step of the interaction influences the action (and reaction) of the other actor. The stages or frames of an encounter must be understood so officers can learn how best to react to a suspect and attempt to de-escalate the situation (Police Executive Research Forum, 2012; Prenzler et al., 2013). The examination of the frames and processes involved in police–citizen interactions will develop a much clearer picture of these very closely watched police–citizen events.

A typical difference between officer and suspect versions of an event can be understood by the following scenario (Alpert and Dunham, 2004). A suspect who claimed he was taken to the ground by the police who grabbed his hair and smashed his head onto the cement, causing serious injuries, files a complaint. The arresting officer answers by saying while he was chasing on foot a fleeing suspect, he tackled him and as they were falling to the ground, the suspect hit his head on a table causing the injuries. As there were no witnesses and the medical doctor reported that the injuries were consistent with either version, it is not clear what really happened. As in most of these 'he said, she said' scenarios, the officer's version becomes the official one (Noble and Alpert, 2009).

In most cases that have no strong evidence, such as a video recording or unbiased witnesses (Rojek et al., 2012), suspects report that the level of force the officer used against them was more than reported by the officers and was more than necessary. They also report quite often that they were not resisting at the level reported by the officer. Their version relates to issues of procedural justice. Juxtaposed to their version of the events, officers report, for the most part, that they used minimal force to control the suspects and do not mention using force after a suspect is under control. It is not likely that an officer will admit to using excessive force against a suspect. The officers report that their behavior followed policies, procedures, and the law. Not surprisingly, the officers often report a suspect using great and sometimes superhuman strength to resist and that the suspect would not stop fighting, which justifies their use of force and perhaps increased level of force as necessary and reasonable. We have learned that what we discover about these interactions must include information beyond a single version, whether the officer, suspect, or eyewitness. Recently, understanding police use of force has shifted to involve the availability and impact of technologically advanced weapons.

Technological Advancements

The development of OC spray and CEWs has changed the landscape of police use of force. Before these new tools became available to the police, officers had only their interpersonal skills, hands, fists, batons (and other weapons of convenience), and firearms to take suspects into custody. As technologies advanced, officers became better prepared to distract or use different types of pain compliance devices and types of force to

control suspects. Along with the innovative tools, came new problems (Smith and Alpert, 2000).

The uses of OC spray and CEWs by the police have similar histories. As OC spray became a popular tool for police in the 1990s, its use generated concerns about its abuse and lethality. Several advocacy groups, including the American Civil Liberties Union and Amnesty International, claimed its use was 'causing' severe injuries and in-custody deaths (American Civil Liberties Union of Southern California, 1995; Amnesty International, 1997). These claims encouraged research that investigated the safety and effectiveness of OC spray and resulting injuries (see Kaminski et al., 1998). Overall, the use of OC spray was determined to be quite effective (see Smith and Alpert, 2000) and its use was correlated with a reduction of injuries to both officers and suspects when compared to traditional 'hands-on' police use of physical force.

During the past few years, there has been a similar pattern of concern raised about the use of CEWs. Although there has been an explosion in the use of CEWs, research findings are just beginning to inform policymakers and trainers about best practices and potential problems (Alpert and Dunham, 2010; Police Executive Research Forum, 2011). In the majority of CEW applications, the application is successful as officers apprehend suspects without significant injuries to either them or the suspect. This leads to important claims that the availability and use of the CEWs assists in the safe apprehension of suspects. Although there is little doubt that the CEW is a popular and useful tool for the police, many questions remain. First, where should it be placed on a use of force continuum, or under what conditions is it an appropriate tactical choice? Second, how many applications are reasonable before turning to another tool or tactic? Third, does the application of electric shock impair the cognitive abilities of a suspect after the electricity is turned off? Fourth, does multiple application or prolonged use of the CEW cause injury or death in certain situations? Fifth, do officers resort to using a CEW too quickly and too often in an encounter as a substitute for lower levels of force? And sixth, does the ease of use or level of pain created by the weapon create an overreliance on it in lieu of hands-on policing, or the 'lazy cop syndrome?' Although many questions about the use of a CEW remain, CEW use continues to help the police manage encounters with suspects.

Research has shown that there are many ways to manage a police–citizen encounter. In a perfect world, there would be no need for the use of force, as citizens would comply with all requests from the police, and those requests would not put citizens at risk. As the world is not perfect and police–citizen encounters can result in force, we need to understand the reasons that there is conflict between the actors. The final section of this article proposes a framework to understand these interactions and why some result in the use of force.

Authority Maintenance Rituals: A Conceptual Framework to Understand Police–Citizen Encounters

The behavior of a police officer is greatly influenced by the nature of his or her interactions with citizens. Similarly, these citizens are likely to react to the officer's actions, comments, cues, and demeanor. Therefore, considering the interactive nature of police–citizen encounters is critical if the behavior of both officers and suspects is to be understood. Although research findings help us appreciate discretion and specific actions, studies have been generally limited to attitudes, personality traits, and demographic and situational characteristics of people and places. Unfortunately, theoretical and conceptual linkages among these behaviors are noticeably absent. We developed the 'authority maintenance theory' to explain the interactive processes involved in police–citizen encounters, with a focus on those that result in the use of force (for a discussion of the developed theory, see Alpert and Dunham, 2004). The term 'authority maintenance' captures the crucial role that authority has in police–citizen interactions, and stresses the officer's ritual to maintain an authoritative edge during any confrontation.

The authority maintenance theory is premised on theoretical strands from Blumer's (1937) symbolic interaction and Homans' (1958) exchange theory. Since these early concepts were developed, social scientists have integrated the concept of power (Emerson, 1972) and reciprocal exchanges (Molm et al., 1999) into these relationships. Sykes and Clark (1975) developed the deference exchange theory to study all police–citizen interactions, which is a necessary element of the authority maintenance theory. Police–citizen encounters turn on the officer's exercise of authority (coercion) and the citizen's submission to that authority (deference or resistance). Deference is only one response to authority. Other responses exist and range from submission to violent resistance. Deference exchange theory focuses only on deference, but the authority maintenance theory includes all behaviors across the deference–resistance continuum. Our theory explaining police–citizen interactions and their outcomes of force includes seven propositions (these propositions are taken from Alpert and Dunham, 2004, where they are explained fully) that account for the unique nature of police–citizen encounters, including the concepts of the asymmetry of authority and the breakdown of reciprocity.

Propositions

1. Police–citizen encounters must be understood as an interaction process, rather than as discrete events.
2. Police–citizen encounters are unique types of social interactions because the major criterion regulating the interaction is the balance of authority or power among actors.
3. Police–citizen encounters are more asymmetrical with respect to authority than most other types of interactions.
4. Police–citizen encounters are a unique type of social interaction because expectations and behaviors often violate the principle of reciprocity.
5. Officers respond to goal blockage with varying degrees of regulation depending upon the type of blockage.
6. Citizens respond to goal blockage with varying degrees of resistance.
7. The resistance/force sequence escalates until one party changes their expected goals voluntarily or involuntarily.

An Integrated Theory

The theory of authority maintenance is based on the notion that police–citizen encounters are interactive and asymmetrical with respect to authority. In other words, behavioral cues and responses to these cues are guided by the respective actor's power and status as well as his or her decision-making abilities and experiences (Alpert and Rojek, 2011). At the heart of the authority maintenance theory is the third proposition on the asymmetrical nature of police–citizen contacts. This supports the notion that an officer will use greater force when his or her authority is significantly challenged by the actions of a suspect. Future research should incorporate perceptual measures of authority from police officers that include the nonverbal gestures, dress, and demeanor of citizens. Debriefing officers after use of force incidents to describe their perceptions would provide important information on how to best operationalize the concept of authority and manage decision-making skills.

The authority maintenance theory goes beyond use of force, as suggested by the principle of reciprocity. Research is needed to identify the factors that trigger the breakdown of reciprocity in police–citizen encounters and result in negative outcomes, including the use of force. The social world of policing is composed of communication through ongoing processes or messages, many of which are threatening to other actors. During encounters, police and citizens must interpret and respond to these messages and incorporate them into their decisions. Peter Manning's (1977) use of 'drama,' or the presentation of behavior that sends a message to another actors, sets the stage for police training and role-playing.

Conclusion

Our effort to understand why, when, and under what conditions police use force is underscored by the critical role it plays in society. We have learned from previous research that there are more questions than answers, but we are learning how to investigate properly many of the issues raised over the years by researchers and policymakers. Police–citizen encounters that result in the use of force can be understood by a conceptual and theoretical framework that we call authority maintenance. This framework provides a way to comprehend why some people make certain decisions and respond in certain ways. Although this theoretical framework provides a way to look at police–citizen encounters, it does not provide all the answers. We are still searching for the reasons why some officers and suspects make decisions that challenge, coerce, or threaten other actors, and why the outcomes of these interactive encounters cannot be predicted successfully.

Abstract

Policing organizations and activities are an important component in the wider constellation of crime control and criminal justice in society. This article reviews fundamental aspects of policing in terms of the following categories: the history of police systems; the functions and organization of policing; the relationship between policing and the community, including its cultural dimensions; the styles and strategies of policing and the role of technology; and the impact of globalization on the form and content of policing.

Policing refers to the whole of structures and processes that are associated with the control of crime and the maintenance of order in society. The history of the police function is not stable over time, and policing models and activities are not identical across societal contexts. The use of the term policing is itself not universally valid as other languages have no equivalent one-word expression for the activities associated with the police function on the basis of the verb associated therewith, and instead exclusively rely upon the noun police or a similar term. Additionally, it should be noted that the concept of police in the social sciences is conceived of as an institution (police in the singular), whereas in everyday language the police is more typically understood as referring to the whole of the body of men and women who occupy a particular position (police in the plural). Despite conceptual and associated institutional variability, trends can be observed toward the delineation of policing in association with crime and order objectives. The so-called private policing refers to security functions that are fulfilled, in more or less legally restricted ways, by privately owned companies and will not be further considered in this article.

Sociologically conceptualized within the broader field of the study of social control, defined as the societal mechanisms involved with the definition of and response to deviance and/or crime, the social reality of policing has been explored in relation to a variety of manifestations and patterns of change and continuity. The majority of insights into the social form and function of policing has come from sociology, with related issues having been explored in history, political science, anthropology, and other social and behavioral disciplines. The specialized treatment of police in the emerging fields of criminology and criminal justice has brought about additional insights concerning the administration of police as an applied field of study.

History

Historically, most societies have had some form of police institutions and policing activities for a long time, developing in relation to changing conceptions of government and other forms of authority (Bayley, 1985; Fogelson, 1977; Manning, 1977; Palmiotto and Unnithan, 2011; Skolnick, 2001; Walker, 1977). For much of early civilization, policing practices were informally organized and largely considered a private matter that consisted of little more than groups of citizens banding together to perform local watch duties as a means to protect their community from outsiders. As societies evolved and developed from simple mechanical and typically small communities, in which members are collectively responsible for the adherence to shared values, into complex organic and much larger states, in which specialization and interdependence become prevalent, a range of more formal and institutionalized forms of social control developed.

In the West, the last few centuries of the Middle Ages witnessed a period in which several European kings began to appoint public officials to formally assume an administrative role in the enforcement of laws. Yet policing duties were still mostly assigned to ordinary citizens, who remained largely responsible for their own protection and well-being. It was not until communities began to become more organized in the form of cities and national governments, along with complex social changes in the social fabric, that the organization of formal policing practices and institutions emerged.

Turning to modern times that began with the rise of the national state, the police function not only became more fully institutionalized, it also and importantly changed in meaning. Max Weber (1922) famously defined the state in instrumental terms with respect to the monopoly that is claimed in a political community over the means of legitimate physical coercion, including military and police as the two major, respectively externally and internally directed, components. However, the conceptual connection between police and politics, not to mention the deceptively obvious common etymological origin of both words, should not lead to overlook the fact that police and politics are variably (dis)connected (Deflem, 2002).

In the European context of national states of a strongly autocratic nature during the eighteenth and nineteenth centuries, police were closely aligned with the attempts of autocratic regimes to maintain power. Thus, policing primarily implied activities associated with the control and suppression of political opponents, such as the growing number of democrats, socialists, and other proponents of ideological political systems associated with ideals of democracy and political justice. As national states underwent processes of gradual democratization, the police function expanded and changed qualitatively.

Within the Western world and increasingly, with the march of globalization, also in other nations affected by developments or pressures originating there from, the police function has rationalized over time, concomitantly with the democratization of national states, in the form of the modern bureaucracy (Deflem, 2002). Manifesting a broader trend of societal rationalization toward the adoption of efficiency standards at the exclusion of other principles of conduct, bureaucratized policing practices are qualitative, different from premodern forms with respect to both means and objectives. Specifically, the means of policing became geared toward the reliance upon purposive-rational standards, such as scientific methods of criminal investigation and other aspects of police technique, while the objectives of policing became gradually detached from the political goals associated with the might of national states in favor of the development of distinctly criminal enforcement objectives.

Thus, modern policing is not only increasingly based on efficiency principles, it also becomes gradually detached from politics. Although the separation of police from politics is never absolute, the modern police function has rationalized in this particular manner in those societies that are democratically organized and that have achieved a modicum of peace. Conversely, under conditions of an absence of or decline in the democratic qualities of government in states or under conditions of warfare and similar occurrences of extreme societal upheaval, police institutions face pressures to once again align more closely with politics.

Functions and Organization

The functions of policing are not exclusively related to the understanding of police as law enforcement (Bittner, 1990; Manning, 1977; Palmiotto and Unnithan, 2011). Although many contemporary societies have organized police institutions that are formally referred to as law enforcement agencies, policing cannot rightly be conceived in terms of the enforcement of law alone. In the centuries leading to the formation of European national states, the policing function was very broadly conceived on the basis of a system of a concept of government that included many different objectives related to well-being, welfare, and the health and happiness of people (Deflem, 2002). Policing thus included a wide variety of social roles intended to regulate human interaction and maintain the social (rather than merely the legal) order in matters as diverse as crime and murder, health, fire, education, religion, and trade.

Over time, policing gradually became restricted to criminal enforcement duties, while other social security functions were delegated to specialized institutions no longer conceived of as police, such as fire brigades and food inspection agencies. The contemporary, more delineated conception of police in terms of crime control relates to the fact that police are authorized to enforce formal sanctions against acts of deviance that have been explicitly codified in systems of criminal law. Controlling crime, only formal police institutions are allowed, under specified circumstances, to rely on force, including deadly force. Broader policing functions, however, remain even in modern times, such as in the case of the regulation of traffic and the delivery of other social services.

A high degree of professionalization is an additional characteristic of modern police (Walker, 1977). Uniformed police officers have become the typical representatives of policing in agencies that are organized as paramilitary, hierarchically ordered organizations. The degree of the military nature and style of formal police institutions to this day vary across societies. In continental Europe and nations with policing systems imported there from, police can be very militaristic and highly centralized as a close ally of the military. Prototypical of these organizational forms are the French force of the *gendarmerie* and similar such military-style policing organizations in other continental nations. In recent times, there has been a trend in these societies toward a demilitarization of policing in favor of an elaboration of civilian police models, especially at the local level, which coexist with earlier developed national police systems.

Other nations, notably the United Kingdom and the United States, have a police system that originates from distinctly civilian forces that were primarily organized on a local level (Dempsey and Forst, 2014; Mawby, 1999; Palmiotto and Unnithan, 2011; Skolnick, 2001). In the United States, the sheriff is prototypical of this form. In the United Kingdom, professional police organizations began to develop from the mid-eighteenth century onward alongside of important societal changes, especially industrialization, increasing crime, and urban social disorder. In 1829, British Parliament passed the London Metropolitan Police Act, which created a civilian police force for the city of London. Led by Home Secretary, Sir Robert Peel, the new professional force was based on the notion that a cooperative relationship should exist between the police and the community they are meant to serve. Although initially seen as an external and hostile force, the new police organization gradually found acceptance among the citizenry and the system was adopted throughout the country.

In the United States, policing in colonial America embraced a night-watch system that was borrowed from the British and first established in Boston in 1636. Although the system initially spread to other large cities along the east coast, eighteenth-century developments of industrialization, immigration, and an upsurge of incidents of disorder, especially of crimes related to a general increase in mobility, brought about an elaboration of police institutions at different levels of government (local, state, and federal) without a national police that has jurisdiction over the whole of the country. Instead, local policing in the United States is executed at the municipal and county levels, administering social control over a limited jurisdiction in view of a variety of tasks, including service, order maintenance, crime control, and peacekeeping functions. In all the US states except Hawaii, state police agencies have jurisdiction over the whole of their respective state, with special concern for highway patrol, criminal investigation, and local law enforcement assistance. At the federal level, an increasing number of US law enforcement agencies has come to exist, each with narrowly defined and highly specialized enforcement tasks.

Community and Culture

Intimately related to its social control function, the police enjoys a special relation to the community of citizens it is

meant to protect and the cultural dimensions of both the police force and society at large. To some extent, police institutions will develop a structural position and cultural disposition that is uniquely tied to its function and organization, but at the same time policing will reflect broader societal characteristics of the structural and cultural context (Bayley, 1985; Scott, 2009; Skolnick, 2001).

With respect to the relation of policing to the wider community, police officers can be perceived in variable ways as either more distant from or more closely aligned with the citizenry. This relative degree of distance and proximity is influenced by structural characteristics, such as the military nature and degree of centralization of the organization of formal police institutions, by culturally conditioned attitudes on the proper and legitimate role of police in society, as well as by situational circumstances related to personal and group experiences with crime and crime control.

Because much police work, especially in the realm of crime control, by necessity must rely on information and other forms of cooperation from the public, it is critical for policing to develop and maintain fruitful relations with members of the community. For this reason, there has been a trend in the past few decades toward the development of so-called community policing strategies that are explicitly aimed at fostering close relations between police and members of the community (Dempsey and Forst, 2014; Greene and Mastrofski, 1991). Unlike traditional policing models in which the police officer is conceived of as a professional whose expertise can create a detachment from the public, the objective of community policing is to build an equal partnership between the police and the community on the basis of mutual trust and support. Beyond a mere improvement of public relations, community policing requires a problem-oriented approach that is based on the specific concerns that exist in a community on diverse matters ranging from crime control to safety issues and various aspects of well-being. The community is thereby ideally involved in both proactive and reactive ways. Modern proactive policing strategies, especially in the United States and the United Kingdom, have witnessed an expansion in recent years in the form of intelligence-led policing, whereby decisions for police to intervene rely upon the assessment of crime risks (Ratcliffe, 2008). Related prevention-oriented models can involve broken-windows policing techniques that adopt a zero-tolerance approach toward minor infractions in order to prevent major crimes from occurring (Kelling and Coles, 1996).

Related to the community structure, policing poses interesting issues in terms of the cultural characteristics of the society in which police institutions are established as well as with respect to the development of a police culture with its own distinctive characteristics (O'Neill et al., 2007). Cultural dimensions of the community influence the effectiveness of policing inasmuch as a degree of legitimacy is by definition required of all forms of authority. The police profession has in this respect typically enjoyed a less favorable standing than the military, especially in symbolic respects, as police officers are in many societies across space and time typically held in less esteem than military soldiers. Additionally, culturally differentiated subsections of society may hold sharply different perspectives of policing. Most notable in this respect are the often-strained relations between police and members of minority communities, such as recently arrived immigrants and a variety of diverse ethnic, religious, and otherwise culturally defined groups.

Among the most striking examples of cultural issues of policing, mention can be made of the organization of policing in the colonial context, the policing of racial minorities, such as African-Americans in the United States, and the policing of minority groups of Arab descent and/or Islamic faith across many parts of the world since the terrorist events of 11 September 2001. As a result, efforts are often made to increase the diversity within police agencies in order to gain a better understanding of minority populations and foster an open dialogue with a diverse variety of community members (Dempsey and Forst, 2014). Such initiatives also seek to address the discriminatory nature of police work that has been found to exist with respect to cultural and other relevant characteristics (Black, 1980).

The cultural aspects of police organizations themselves have been found to be sufficiently specific and distinct from the wider societal context that it is useful to speak of a police culture or a culture of policing (O'Neill et al., 2007; Palmiotto and Unnithan, 2011). The typical characteristics of the culture of policing relate intimately to relevant functions of social control. Police officers may develop an 'us-vs-them' mentality in their dealings with the public, due in large part to the fact that police are typically only called upon when a negatively defined situation occurs, thereby exposing them to the effects of criminal conduct, victimization, violence, and other problematic occurrences. As police agents are also uniquely authorized to use force and, at once, not necessarily treated with respect and understanding, citizens do not always display positive sentiments toward them. In response, a strong sense of social solidarity and cohesiveness promotes an independent police culture segregated from the rest of society. Among the possible negative implications, corruption and other forms of police misconduct may exist without effective ways to redress the problems that are posed (Corsianos, 2012; Sherman, 1978). The infamous code of silence that characterizes many police agencies may additionally prevent accountability.

Strategies and Technology

Besides cooperation with the citizenry, policing activities rely upon a wide range of strategies and technological means that involve different aspects of police work (Dempsey and Forst, 2014; Palmiotto and Unnithan, 2011). In matters of method, various strategies and styles of policing can be differentiated, such as proactive and reactive policing, and overt and undercover police work. In pursuit of investigative objectives, police agencies rely on a number of methods to supervise, control, and gain access to the community. Traditionally, the agents of formal police agencies relied upon minimal tools, such as a nightstick or a baton, and could not maintain communications with one another outside the police station. Advances in technology, in particular the development of police radio systems, would later allow agents to build a communications network. Depending on the style of policing, officers were armed with a variety of weapons. In terms of patrol in the

community, the development of methods such as foot patrol and vehicular pursuit are important elements that shape the variable ways in which policing can be effectively conducted.

Police agencies were historically and are until this day typically organized in distinct locales such as police stations that are responsible for specified jurisdictional areas typically referred to as police precincts. Police can then be contacted and called upon by citizens by such means as police call boxes or emergency phone numbers. Citizen access to police is highly variable across societies and over time and has been found to be a critical component of accountability in policing, especially in democratic societies. In response, policing methods have been developed that rely on rapid-response teams, assisted by two-way radio systems and the extensive use of police cars. Technological advances in telephone technology, particularly the widespread availability of cellular phones, have in recent years brought about a considerable increase in the number of calls to police.

Reactive strategies of policing are complemented by proactive methods meant to prevent or deter crime. The elaboration of proactive methods has gradually been accelerated through the development of methods of citizen support, such as neighborhood watch, seeking to prevent crime from occurring. Additionally, the reliance on technically advanced systems of data gathering and investigative aids has contributed to policing strategies of surveillance that are widely dispersed throughout the society. The installation of video cameras in streets and buildings is the prototypical manifestation of proactive surveillance in many contemporary societies.

Besides security tools and technologies of transportation, policing has greatly been influenced by the development of systems of criminal identification (Deflem, 2002). Originally, modern police organizations relied upon photographs and descriptions of the facial and other physical features of criminal suspects. From the late nineteenth century onward, the use of fingerprints, which were held to be unique and permanent, became standard practice among police. Fingerprint identification data were numerically expressed so that they could be shared among police by means of telegraph. Computerization has eventually brought about digital forms in which data can be stored and shared by means of electronic fingerprinting techniques. In recent decades, DNA identification has been added as the technically most advanced method to identify suspects.

The rise of digital-information computers has brought about important changes in policing (Manning, 2008; Dempsey and Forst, 2014). Many modern police agencies utilize computers at various levels of operations, giving police organizations the ability to tailor technology to supervise the community by means of a wide array of surveillance tools. Additional advanced technologies in contemporary policing include computerized reports, both at police stations and in police vehicles, and crime mapping technologies such as geographic information systems of a variety of variables associated with criminal incidents and crime patterns.

The use of video cameras and other data-collection techniques adds to the intrusive qualities of policing that have historically been most typically associated with covert methods relying on undercover agents (Marx, 1988). Undercover tactics are applied in a variety of settings, typically involving crimes of a hidden nature, such as illegal drug use, or crime taking place in specific communities such as the world of organized crime. The multiple goals of undercover policing include intelligence gathering, crime prevention, and the infiltration of suspect groups. Beyond its investigative objectives, undercover police work involves deception, thus making it, by its very nature, ironic from the viewpoint of the common perception of uniformed agents of social control. Undercover and proactive means of policing have been found to correlate inversely with traditional covert means of policing, the number of restrictions that are placed on the legitimate use of particular reactive methods, such as deadly force, and the extent to which police can legitimately resort to search and seizure procedures without due process and judicial oversight. Among its problematic implications, undercover policing may ironically contribute to an increase in crime by creating opportunities for criminal conduct to occur.

Globalization

Variable in function and organization over the course of history, policing also differs across national states and other delineated jurisdictions in relation to important societal characteristics such as political, economic, and cultural factors. At the same time, general trends and patterns can be observed as well (Mawby, 1999). Globally, the centralized structure of policing is the most common organizational style, existing in the democratic countries of continental Europe but also in former totalitarian regimes such as the Soviet Union. Strikingly, national states with an autocratic past, such as France and Germany, tend to continue to rely on policing institutions in the modern era that can be very similar in form and organization to their historical predecessors.

Developing nations, including countries in Asia and Africa, as well as traditionally Islamic countries employ centralized police systems whereby a central police headquarters, typically located in the nation's capital, has command over all other, subordinate police units (Sadykiewicz, 2005). The centralization of police power can in variable ways coexist with a likewise centralized nature of the accompanying political and legal systems. A decentralized policing structure, conversely, divides enforcement duties among police units at local and higher levels of jurisdictional authority without the existence of a national police. The US system of law enforcement typifies the decentralized policing model, whereby hosts of local, state, and federal agencies operate independently and often have specialized agencies that serve a variety of functions. Considered globally, police decentralization is uncommon except in most industrialized English-speaking countries. Police decentralization is in such national cultures also often associated with the safeguarding of democracy as a political ideal and the preservation of individual rights of liberty, such as the freedom of movement and the free expression of ideas.

In democratic societies, police agencies are important and arguably the most visible institutions in charge of guarding social order, aiding in the socialization of the citizenry, and serving as both moral and legal social control agents that operate under prevailing jurisdictional laws (Bayley, 2005; Sklansky, 2008). Harmonizing with the understanding of

democracy as involving an intimate relation between government and public, the democratic role of police assumes a balance between the authority to enforce laws, on the one hand, and the accountability to the public, on the other. At the same time, police must be responsive to the needs of society while working toward a cooperative relationship with the community. Democratic police organization is therefore often associated with community policing and similar styles of police involving support of the public.

The democratization processes that can be observed in recent decades in several parts of the world have brought out the relative independence of police systems. The transition to democratic systems of policing has indeed proven to be challenging for countries with vastly different political systems, such as the former Soviet nations and formerly repressive police states like South Africa and Iraq. The implementation of democratic principles, where police agencies were once highly politicized to exist as a repressive tool of the state, impedes the support of the public. In cases where there is a lack of financial or technical resources, the likelihood of success to establish accountable systems of police is compromised as well.

The growing interdependence among national states and otherwise confined jurisdictions has historically led to the development of a variety of international policing practices (Deflem, 2002). With the growth of national states in Europe, international policing was initially developed for political purposes to maintain autocratic rule, but gradually began to focus on distinctly criminal enforcement tasks. By the early twentieth century, police agencies of various nations began to develop permanent cooperation structures and the bilateral and multilateral levels, including the formation of Interpol as the International Criminal Police Commission in 1923. In the drastically changed international constellation of the post-World War II era, international policing expanded greatly on a variety of concerns, such as the international rendition of fugitives, the global drug trade, border control, and the importation and exportation of police techniques across national boundaries.

International policing activities take on multiple forms, ranging from very informal to highly structured methods (Casey, 2010; Deflem, 2002; Deflem and McDonough, 2010). Unilateral international and otherwise *trans*-jurisdictional strategies tend to be preferred as police agencies can thereby maintain control over their operations and the proper ways of execution. Cooperative efforts among police at various jurisdictional levels are typically initiated on a need basis, in order to successfully complete a specific investigation, and tend to be limited in terms of the number of participating agencies from other jurisdictions. Organizations of multilateral cooperation, such as Interpol and the European Police Office, can rely on a large number of partners from many different nations, but they are strictly collaborative in nature and do not involve the creation of a supranational police force.

Over the past decade, no matter has affected policing more than the focus on terrorism that has been propelled, more than by any other incident, by the events of 11 September 2001 (Deflem, 2010). In the wake of those attacks, police agencies in the United States as well as many other nations in the world have drastically enlarged and reoriented enforcement objectives toward the suppression of terrorist groups and individuals. In the United States, for example, the Department of Homeland Security has been established to coordinate a multitude of security agencies involved with protecting the borders and security of the country, most notably the newly created US Immigration and Customs Enforcement, which has begun to rival the Federal Bureau of Investigation as the premier federal American law enforcement agency. The policing of terrorism as a criminal law enforcement matter complements other counterterrorism strategies, especially those that are of a military nature and oriented toward the protection of national security interests under the heading of the so-called War on Terror.

In some nations, counterterrorism policing is tightly controlled by centrally organized governments in the furtherance of political power. In many democratic nations, however, police agencies are engaged in counterterrorism efforts on the basis of a depoliticized understanding of terrorism as a form of criminal conduct. Unlike military and related intelligence organizations, police agencies can rely upon extensive networks of international cooperation that are formed irrespective of the differences that may exist among nations in political and other respects.

With an eye toward the future of policing across the world, it can be postulated that policing will unquestionably remain an important component of crime control and order maintenance. Even as globalization processes continue to expand in political, economic, and other respects, policing systems can be expected to continue to exhibit nationally and regionally variable characteristics. Moreover, as the world as a whole and its various national states and other constituent parts can be assumed to further increase in scale and complexity, policing in the contemporary era of globalization will continue to expand and entail multiple forms and strategies in an increasingly intricate manner.

Policing in Divided Societies

Aogán Mulcahy, University College Dublin, Dublin, Ireland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In divided societies, the police tend to be closely aligned with the dominant social group and their actions focus on maintaining state security rather than providing routine policing services. As a consequence, policing often becomes a key axis of conflict and efforts to reform the police are central to the process of conflict resolution. The Patten Report reforms, for example, were a crucial part of the peace process in Northern Ireland and have been widely viewed as a success. However in other divided societies where police reform may comprise part of a peacekeeping intervention or international aid program, the impact of 'security sector reform' measures tends to be less clear-cut, partly because of the scale of the challenges involved, and also because of the difference in the priorities of the 'donor' and the host societies.

Introduction

The term 'divided societies' is used to describe societies characterized by a major schism between different social groups, often arising from their respective and fundamentally antagonistic orientation toward the prevailing political arrangements (Guelke, 2012). Whether arising from ethnic, national, or religious differences, the divisions that mark such societies often take the form of dominant/subordinate relations, with a corresponding and often stark differential in access to resources and the established routes to political power. While Northern Ireland, South Africa, and Israel/Palestine are typically highlighted as iconic examples of 'divided societies', the applicability of this term extends to a range of other societies and contexts, whether in relation to the former Yugoslavia, 'failed states' such as Somalia, or other societies marked by civil war or violent and enduring upheaval.

At the outset it is important to distinguish between 'divided societies' and 'societies with social divisions'. The latter characterization reflects the majority of societies worldwide, where factors including class, race, and gender may each exert a major influence on the ability of individuals to participate fully and equally in society and on the overall quality of the life they enjoy. In various ways, they exert a strong influence on the relationship between different social groups and the police. Although these divisions are tangible and far-reaching, the difficulties surrounding policing are of a different order when a society is structured around the key axis of division.

In divided societies, the dynamics of conflict often revolve specifically around policing and related issues of security and justice for several reasons. First, as an agency of the state, the police (or the public police at least) are symbolically associated with the dominant political order, as well as being a vital expression of its security insofar as their activities are crucial in protecting the state against its enemies, whether within or without. Second, and related to the above, while the police may continue to provide a civil policing service (dealing with 'ordinary' crime), primacy is given to securing the state. Relations with subordinate groups, therefore, are shaped by the view that they are a threat to be managed rather than part of the citizenry to be protected. Third, the nature of such societies ensures that political opposition generates an aggressive policing response; and police policies and behavior in dealing with social unrest or protest may exacerbate the existing divisions, as policies of crowd control or even the sustained surveillance of a suspect community generate further hostility, adding fresh grievances to extant opposition. These factors ensure that "conflict over policing is endemic in these societies" (Weitzer, 1995: p. 5), both as an underlying dimension and a dynamic aspect of the contours of conflict.

The remainder of this discussion is structured in two sections. First, I consider the defining features of policing in divided societies, including the role of nonstate actors in providing security and policing in authoritarian regimes. Second, I highlight the role that police reform plays in processes of conflict resolution, and in distinguishing between internally driven reform processes (using events in Northern Ireland as a case study) and those emanating from external intervention; and exploring the role that dealing with the past plays in the dynamics of this process.

Features of Policing in Divided Societies

Various authors have argued that policing in divided societies is characterized by a set of features that distinguish it from policing elsewhere. Brewer (1991) and Weitzer (1995) have proposed different typologies and these influential models are outlined below (see also Enloe, 1980) (**Table 1**).

Some differences are evident between these two models. Brewer (1991: pp. 181–184), for instance, claims that policing in divided societies is characterized by "chronic and endemic manpower shortage" due to the far-reaching demands placed on the police; "the diffusion of policing functions throughout the dominant group" through the involvement of volunteer or auxiliary groups in the policing role; and "close operational links between the police and the military". Weitzer (1995: p. 299), however, notes that these latter characteristics are "neither common in nor unique to divided societies", but certainly they are evident in some cases. Overall though, Brewer and Weitzer agree on core dimensions: the alignment of the police with the dominant social group against subordinate groups, the deployment of police resources accordingly, and the protracted, negative consequences arising from this.

While divided societies experience inequality and conflict across a range of domains, the issue of policing is uniquely

 http://dx.doi.org/10.1016/B978-0-08-097086-8.96051-3

Table 1 Features of policing in divided societies

Brewer (1991)	*Weitzer (1995)*
• Selective enforcement of the law in favor of the dominant group. • Discriminatory practices which limit the exercise of the rights of the minority. • Political partisanship in upholding and enforcing the distribution of political power by allowing unequal rights to political protest • A lack of autonomy from the political system. • An absence of effective mechanisms of police accountability. • Relatively unrestrained use of force. • A dual role which arises from responsibility for ordinary crime and internal security, although as threats to internal order have grown, security tends to dominate police activities, strategic planning, and leadership. • The polarization of attitudes toward the police and their conduct. • A social composition biased toward the dominant group because of an inability or unwillingness to recruit from among the minority communities. • Chronic and endemic manpower shortage. • The diffusion of policing functions throughout the dominant group, as volunteer groups and other compatible agencies are drawn into the policing role. • Close operational links between the police and the military.	• Systematic bias in law enforcement. • Politicized policing, including strong police identification with the regime and vigorous police action against the regime's political opponents. • Dominant-group monopoly of the top positions in the police force. • Dual responsibility of the police for internal security and ordinary law enforcement. • Legal or extralegal powers giving the police great latitude, including powers in relation to the use of force. • An absence of effective mechanisms of accountability with respect to police abuses of power. • Polarized communal relations with the police, with the dominant group as a champion of the police and the subordinate group largely estranged from the police.

controversial. Again, though it is important to recognize the complexity of the issues involved here, the public can be a highly sophisticated audience, distinguishing between the more value-neutral issues of service delivery and the wider issue of legitimacy. For example, members of the public may express higher levels of satisfaction with the routine overall performance of the police than they do in relation to the police's involvement in public order or state security issues. Satisfaction with routine policing does not translate into acceptance of the police or the legitimacy of their role. Concerns over police legitimacy may be muted or latent in the absence of widespread disorder or an immediate political crisis. But if the political environment becomes more fractious and the issue of policing becomes the focus of attention – for example, through police responses to public protest – then the legitimacy deficit becomes all too apparent and the crisis of the state becomes a crisis of policing. Thus, reflecting on policing and the civil rights movement in the USA, Wright noted the spiraling effects of widespread concerns over policing, which the establishment largely ignored until this could no longer serve as a plausible response:

> once a group experiences exclusion and has no effective way of communicating what is happening to those who are not affected, the police become a lightning conductor. The worst things done by police, which are neither punished nor for which any kind of restitution is made, come to be seen as representative of a society which tolerates or encourages them. The best elements of the police are compromised by their complicity with the worst. And the most provocative amongst the people they are policing are seen to be acting under provocation themselves – a provocation which is conceived as an intent. If all other avenues of trans-ethnic communication and cooperation are absent, the substance of interethnic relations tends to revolve around the antagonistic axis of law and order.
>
> (1988: p. 180–181)

Similarly, in the context of Northern Ireland, Whyte (1990: p. 88) noted that Catholics and Protestants disagreed more over the "unhealed sore" of policing and security policy than they did on constitutional issues. The biggest disparity he found between Catholic and Protestant views in any public opinion survey, was not on political preferences but rather on the use of plastic bullets, a particularly controversial aspect of security policy, following the death of several members of the public after being struck by plastic bullets.

In highlighting these issues, it is important to bear a number of qualifications in mind. First, even in the most difficult environment, some level of 'normal' or 'routine' policing usually persists. In fact, 'routine policing' might even typify the nature of policing in communities which are at some remove from frontline conflict zones (Brewer and Magee, 1991). Second, there is a danger that the focus on intergroup relations overlooks internal divisions within either the dominant or the subordinate group. For example, while the dominant social group is likely to be largely supportive of the police, this is not always the case. Some communities within the dominant group may harbor serious concerns about police effectiveness and efficiency. For example, Hasisi and Weitzer (2007) demonstrate that whereas the Israeli-Palestinian conflict shaped public attitudes toward the police in significant ways, with large differences between the views of Jews and Arabs, substantial differences in opinion were also evident within the minority Arab community. In other contexts, pro-state groups may harbor deep concerns over police misconduct but may feel inhibited from expressing them, lest this be used to criticize and possibly undermine 'their' police (Weitzer, 1995).

Policing and Authoritarian Regimes

While the term 'divided societies' may imply a level of overt conflict, in reality many divided societies may be better

described by stability, albeit a stability arising from explicit domination and the threat of violence. In totalitarian or authoritarian states, for instance, the incumbent regime typically relied on an extensive state security apparatus to maintain control (supported by ideology and patronage, among other things). In the former Soviet Union, policing had an explicit political dimension, and police activities were directed against those who were perceived to pose a threat to the state (Shelley, 1996). Even the policing of low-level crimes of 'social disorder' was driven by an explicit concern that this posed a threat to the well-being of the wider society and to Soviet ideals (Shearer, 2009). The scale of security policing under these authoritarian regimes was enormous. Not only did it involve a large body of personnel, it also extended to a vast project of surveillance. The files of the STASI, East Germany's state security police, stretched for well over 100 km of shelf-space, and 174 000 people were identified as informants (2.5% of the population aged 18–60 years). Estimates suggest that the true number of informants could be significantly higher (perhaps by a factor of three of more), and that does not include those who were only occasional informants (Funder, 2004; Koehler, 2000. See also Browder's, 2004 discussion of policing in Nazi Germany).

The transition from such authoritarian regimes to a more democratic form of government inevitably brought issues of police reform to the fore. In addition to concerns over security policing, civil policing was also highly problematic and was characterized by a combination of routine misconduct, lack of accountability, bribery and corruption, and mistrust. In different former soviet societies, the legacy of this situation persists. Efforts to reform the police have proven limited in impact and levels of trust in the police remain relatively low, which itself may mirror low levels of trust in state institutions generally in post-Communist societies (Beck and Chistyakova, 2002; Beck and Robertson, 2009; Light, 2014; Semukhinaa and Reynolds, 2011; Shelley, 1999).

'Alternative Justice' in Divided Societies

The dynamics of policing and security in divided societies leave a considerable lacuna in terms of security provision. The focus on state security absorbs considerable policing resources; and hostility between the police and marginal groups leads to difficulties in conducting routine policing, including a paucity of information provided to the police (on whom they are dependent to investigate crimes successfully) as well as the physical dangers posed to the police. In those circumstances, public concerns over 'ordinary crime' can be considerable; and even though the demand for policing may be acute, it is not delivered at an appropriate level or to an adequate standard. The situation is further complicated by the use of criminals as informants by the police or security forces, as well as by concerns that communities opposed to the state are in effect punished for their stance by active neglect on the part of the police. Thus, providing a policing solution of sorts can be an important facet of the activities of nonstate actors.

The manner and extent to which this 'policing vacuum' is addressed varies from society to society, and while it may be relatively haphazard in some societies, in others it may evolve into a (relatively) structured system of 'alternative justice' (see, generally, Abel, 1982). In Northern Ireland, for instance, Republican and Loyalist groups each provided a system of 'alternative justice' during the conflict and beyond, incorporating a loose tariff of punishments – varying in prevalence over time and according to the wider political context – including punishment shootings (often 'kneecapping' of the victim), punishment beatings, banishment, shaming, and so on. The dynamics of this alternative justice system are highly complex. While it accrued a degree of political capital for those involved in administering this system, it also diverted resources away from what many paramilitaries viewed as their *raison d'etre* – violent opposition to or support for the prevailing state arrangements – and led to outraged criticism of the groups involved for the sheer brutality inherent in such punishments. The systems operated by Republican and Loyalist groups tended to reflect their different organizational structures as well as their respective relationships to the state. Republican groups tended to be more hierarchical in command structure. Loyalist groups, by contrast, tended to be less centralized and more loosely organized in structure, allowing for greater variation in the use of paramilitary punishments from group to group, while also allowing greater scope for these punishments to be used to settle personal scores rather than address crime specifically. While one of the untold stories of the Northern Ireland conflict lay in the difficulties and complexities of relations between Loyalist communities and the police, these difficulties were not of the same order as those found in Republican areas. Quite simply, there was not a sufficient gap in the policing market for Loyalist groups to operate a system of alternative justice that could generate the same levels of legitimacy that the Republican groups obtained.

In other settings, the inadequacy of the police response may lead various groups to resort to private security services to provide the level of policing/security they want, whether to protect their own personal security or specific commercial/corporate interests. In divided societies, however, the resort to private security is significant given the often highly militarized level of policing that such private contractors provide, and the lack of oversight characterizing their deployment (see, for example, Newburn, 2007; O'Reilly, 2010).

Political Transition and Police Reform

While policing is a key dynamic of conflict in divided societies, it is important to recognize that societies are not condemned to eternal conflict. Scope may exist to resolve the underlying issues and provide appropriate remedies through the development of political arrangements that can command widespread political support. Indeed, policing and 'security sector reform' generally loom large in any peace process and form a key dimension of negotiations and any ensuing political agreement. Police reform initiatives tend to occur through internal processes of political accommodation or through the intervention of outside parties and the deployment of external agencies.

Police Reform and Internal Agreement

One of the most prominent examples internationally of police reform is the recent case of Northern Ireland. The 1998 Belfast

Agreement outlined the basis for a political agreement to resolve the Northern Ireland conflict. Under this agreement the Independent Commission on Policing (ICP) – chaired by Chris Patten – was established, and its 1999 report laid the basis for a major transformation of the policing landscape in Northern Ireland. The ICP's recommendations were not oriented to the specific political circumstances prevailing in Northern Ireland at any one particular time, but instead focused on addressing "the challenge confronting policing in any modern society" (p. 6). Their recommendations were designed to be consistent with five key principles: "Does this proposal promote effective and efficient policing? Will it deliver fair and impartial policing, free from partisan control? Does it provide for accountability, both to the law and to the community? Will it make the police more representative of the society they serve? Does it protect and vindicate the human rights and human dignity of all?' (p. 5).

Overall, the report's most prominent recommendations coalesced around a number of key themes (see Table 2 below): to enhance accountability, oversight, and governance; to work in partnership with the community and to devolve decision-making to the lowest level possible; to embed human rights within the structures of policing; to make the police more representative of the population of Northern Ireland; and to make its culture and ethos more inclusive.

The ICP's most significant recommendations addressed issues of governance, accountability, and oversight through the establishment of new structures which would embed accountability in the institutional landscape of policing in Northern Ireland. In terms of governance, the ICP proposed that a 'Policing Board' replace the existing and largely ineffectual Police Authority, with the function of holding the Chief Constable publicly to account, and agreeing and monitoring the implementation of a policing plan; the Board would also be given powers to initiate inquiries and to require the Chief Constable to report on any issue.

At local authority level, a system of 'District Policing Partnership Boards (DPPBs)' was to be established, comprised of elected and independent members, and 'advisory, explanatory and consultative' in function (p. 35). Importantly, the ICP called for these to be given tax-raising powers of up to 3% (similar to the powers already available to District Councils for economic development) to purchase additional policing services if required, whether "from the police or other statutory agencies, or from the private sector" (p. 35).

The ICP endorsed an earlier recommendation that an independent police complaints system be established in the form of a 'Policing Ombudsman'. This would also have the power to investigate policies or practices where there was a public interest in doing so. To ensure that the reform process itself was fully implemented, the ICP called for the appointment of an 'Oversight Commissioner' with the explicit function of monitoring and reporting on the progress made in implementing the ICP recommendations. Underpinning this emphasis on oversight and accountability was an explicit commitment to embedding *human rights* within all aspects of policing, including training and appraisal. The report recommended a new oath and code of ethics and the appointment of a human rights lawyer to advise the police.

The ICP noted the complex nature of the many problems the police faced, but in seeking to address these effectively it called for a new model of 'policing with the community', a fundamental partnership between the police and the public. As it noted:

> it is not so much that the police need support and consent, but rather that policing is a matter for the whole community, not something that the community leaves to the police to do. Policing should be a collective partnership: a partnership for community safety.
> (p. 8)

It stated that 'policing with the community should be the core function of the police service and the core function of every police station' (p. 43), and that police decision-making should be devolved to the lowest level possible.

The ICP noted argued that through sustained efforts the police should be made more representative of the wider population, particularly Catholics who comprised 8% of the force in 1999 (at a time when Catholics nearly comprised half of the overall population). It proposed a new recruitment strategy to increase Catholic representation within the PSNI to approximately 30% (which the ICP appeared to view as a 'critical mass' figure) within a 10 year period. This entailed a system of '50:50 recruitment' whereby applicants who met the entry requirements would be placed into two separate pools of Catholics and Non-Catholics. Applicants would be ranked within each pool and an equal number of recruits would then be selected from each. Simultaneously, the report called for a significant

Table 2 Patten report – selected recommendations

Accountability, governance, and oversight	Policing Board to replace the existing Police Authority.
	District Policing Partnership Boards to be established at local authority level
	Police Ombudsman to be established as an independent agency to investigate police complaints
	Oversight Commissioner to monitor implementation of ICP recommendations
Human rights	New Oath
	Human Rights to be embedded within all training
Policing with the community	Policing with the community to be established as core function of the police
	Neighborhood policing teams to be established
	Decision-making to be devolved as much as possible
Size and composition	Reduction from approximately 13 000 full-time officers to 7500
	Introduction of 50:50 (Catholic:Non-Catholic) recruitment scheme
Culture and ethos	Royal Ulster Constabulary to be renamed
	Symbols to be inclusive

reduction in the overall force size, from 13 000 officers to 7500, which would be achieved specifically through a generous severance scheme. The report also recommended that the force be renamed – in 2001 it became the Police Service of Northern Ireland (PSNI) – and that 'force symbolism' should be neutral in terms of political affiliation.

The Chairperson of the Northern Ireland Policing Board lauded the reform program as a "blueprint for democratic policing anywhere in the world" and described the PSNI as "the most scrutinized and accountable police service probably anywhere in the world today" (see Bayley, 2008; Ellison, 2007; Mulcahy, 2013), while Chris Patten (2010: p. 25) described the PSNI as "the best working example of how to police a divided community". Such acclaim runs the risk of overlooking, among other things, the political antagonism which characterized the implementation of the Patten reforms, as well the ongoing difficulties in translating the report's focus on policing with the community into practice (see generally Ellison and O'Rawe, 2010; Mulcahy, 2013). Nevertheless, the police reform process in Northern Ireland quickly assumed the mantle of a success story, particularly for its establishment of a robust model of police governance and oversight.

If Northern Ireland, albeit with qualifications, stands as a success story, the development of policing in post-conflict settings is by no means a smooth process. In the context of South Africa, for instance, Brogden and Shearing (1993) and Marks (2005) highlighted the considerable difficulties involved in moving from a heavily militarized mode of policing to a civic oriented one. Conducted under a significant amount of international scrutiny, the reform program involved major institutional changes as well as extensive training and a turnover in personnel. Nevertheless, Ivkovic and Sauerman (2013) found that even two decades after the formal ending of the apartheid regime, a notable minority of officers did not recognize even the most severe forms of police corruption as violations of official rules. Baker (2002) links the state's failure to provide adequate public policing to the continuation and proliferation of nonstate forms of policing that sought to provide the security that the state did not, particularly as levels of violent crime remained extremely high and amidst the dawning realization that the end of apartheid did not guarantee any significant improvement in the living standards of the population. Private security in this context, however: "permits the continuation of authoritarian values and practices; divides communities on the basis of their ability to secure alternative policing for a failing state provision; and nurtures the view that the rule of law is more of an obstacle to maintaining social order than an effective guarantee of it" (Baker, 2002: p. 51). Such claims might not hold in every circumstance, but they nevertheless highlight the dangers of transitional processes and the centrality of security provision therein.

Security Sector Reform and External Intervention

In many conflict zones or transitional societies the issue of police reform is part of a wider process that often reflects a variety of international interests and interventions, due to the sheer scale of conflict and division that exists and the corresponding scale of the challenges that this poses. In 'developing democracies', for instance, Hinton and Newburn (2009: p. 6) argue that the public sphere tends to be characterized by: "weak democratic institutions"; "corruption and weak rule of law"; "significant levels of poverty and inequality"; "high crime and political instability"; and "poorly institutionalized channels of police accountability and responsiveness". In such circumstances, where routine law and order may have broken down, the challenges for policing are considerable. As Grabosky notes: "In many weak and failing states, and in other post-conflict situations, there may be no functioning police agency. Alternatively, the police in the host country may be corrupt, incompetent, abusive, or some combination of the three. Thus there is often a need for external assistance in building or in rebuilding an indigenous police service" (2009: p. 101). In violent contexts, police from a variety of countries may form part of international peacekeeping missions and police reform typically forms part of a wider program of 'security sector reform' (Greener, 2011).

The growth of interest in 'security sector reform' and the development of democratic policing worldwide arises from a number of factors. First, the success of development and aid programs, and even of political agreements, has increasingly come to be seen as dependent on ensuring basic levels of security (Bayley, 2005). Second, it reflects a heightened concern over insurgency and radicalism in the aftermath of the attacks of 11 September 2001 (9/11) on the United States. Third, the sphere of policy development is increasingly international in scope and characterized by greater attentiveness to 'policy transfer' and 'lesson drawing' between jurisdictions, which itself is underpinned by the rapid growth of the private security sector and the development of an international policy elite offering 'solutions' to police/security problems (O'Reilly, 2010).

International interventions have taken place in diverse contexts, and prominent examples include initiatives by the European Union and other bodies in the former Yugoslavia (Aitchison and Blaustein, 2013; Celador, 2008), as well as Australian-backed interventions in a variety of Pacific conflicts (Dinnen and Allen, 2013; Goldsmith and Dinnen, 2007). The provision of appropriate assistance, however, is complicated by various factors. First, in societies often characterized as 'weak or failing states', 'donor' societies may contribute to humanitarian and reconstruction programs partly to prevent the development of humanitarian disasters. However, this typically coincides with issues of donor self-interest, such as preventing the development of a political vacuum in which radical groups could flourish or the destabilizing effect that a conflict could have across an entire region e.g., through refugee flows as the spillover of violence (see, for example, Newman, 2010).

Second, the impact of external interventions is uncertain and contingent. This reflects "inflated expectations for police reform [which] are frequently trumpeted by domestic politicians and international policy elites, regardless of how staggering the rates of crime, how politicized and heavy-handed the police force, and how corrupt and lawless the government that is meant to enact and monitor the proposed reforms" (Hinton and Newburn, 2009: p. 1–2). It also reflects the general absence of long-term evaluations of such processes, and in effect, a default understanding of success in terms of the establishment of new institutions or training programs, rather than the impact they have on the wider social landscape of security and justice (Ellison and Pino, 2012).

Third, the eagerness with which western powers lecture transitional societies about 'international best practice' policing arrangements does not seem to be accompanied by a careful analysis of the specific needs of each society but rather by an assumption that Western models of police reform – relying heavily on vague models of 'community policing' – are the obvious 'solution' (Ellison and Pino, 2012). As Hills (2009) pointedly noted, external agencies tend to prioritize 'security', whereas local residents prioritize 'order' at an everyday level. Indeed, the involvement of international peacekeepers and initiatives to enhance the professionalism of the indigenous police can be counterproductive insofar as it can further undermine the reputation of the local police and lead to greater levels of dependency on international peacekeepers and other external parties (Dinnen and Allen, 2013).

Dealing with the Past

The legacy of the past is a formidable challenge for any society emerging from a period of conflict. Not only is the sheer scale of the conflict's human cost a major hurdle in its own right, but this is further complicated the covert nature of the protagonists' actions, the use of 'proxy' actors to pursue goals (Jamieson and McEvoy, 2005), and widespread strategies of 'othering' and 'denial' (Cohen, 2001). Yet the demand for justice and disclosure ensures that strategies to deal with the past often form a key dimension of the processes of conflict resolution. The South African Truth and Reconciliation Commission is probably the most renowned example of this, and while it was characterized as a means of laying bare the past and thereby providing a basis for political reconciliation, in its detail it often comprised a harrowing catalog of policing practices and the workings of the state security apparatus. The TRC was based on the simple premise that individuals providing full disclosure of their actions would be granted immunity from prosecution. This immunity was, in effect, presented as the price of political progress (see generally, Hayner, 2010).

In Northern Ireland, by contrast, the legacy of the past presided in its absence. Although this issue dominated popular debate and shaped in far-reaching ways the relations between the various parties that comprised the power-sharing executive, the British Government remained largely hostile to any formal process of truth recovery. While allegations surrounding different policing controversies formed one aspect of this debate (Lawther, 2010), one way in which some of the wider issues surrounding the conflict have been addressed is through the PSNI's establishment of a Historical Enquiries Team to investigate the approximately 1800 unsolved killings from the conflict, creating specific units to review police investigations and any available evidence. While there was a possibility of individuals being charged as a result of this review, it most cases it simply provided more information which could be relayed to the victims' families and thereby provide some form of closure. Yet as Lundy (2011: p. 102) notes, this format is more appropriate to truth recovery in respect of individual cases, than to investigating the 'macro-truths' relating to wider practices and policies of the various protagonists around which so much of the debate on the past has focused. The focus on policing the past has, however, proven costly, both in terms of absorbing scarce financial resources as well as in diverting political focus away from the need to agree on shared priorities for the future (Oversight Commissioner, 2007). These tensions highlight the manner in which current institutions can become enmeshed in the controversies surrounding legacy issues and this may remain the case until decisive steps are taken to embark on a society-wide process of truth recovery that provides an adequate means of resolving them.

Conclusion

In divided societies, policing is a uniquely controversial issue that often mediates the relationship between entire communities and the state. Typically, the police are closely aligned with dominant social groups and police resources are deployed accordingly against subordinate groups. The model of policing this generates is one characterized by close links between the police and the political sphere, policing strategies that are heavily reliant on controversial public order tactics and lacking in oversight, and deeply polarized experiences of and attitudes toward the police.

These difficulties have generated considerable interest in how policing in divided societies may be reformed. While recent developments in Northern Ireland – and particularly the template provided by the 1999 Patten Report – are often cited as an example of successful reform, especially in relation to oversight and accountability, in many other instances of police reform the outcomes are much more qualified. The impact of external interventions and the linkage of police reform to development aid programs is unclear and it has been heavily criticized for failing to pay due regard to the specific needs of individual societies. Even in wider processes of political transition, the significance of policing is evident through the shadow it casts on processes of 'truth recovery' and other measures to deal with the past.

Policy Analysis

Aidan R Vining, CNABS, Simon Fraser University, Vancouver, Canada
David L Weimer, University of Wisconsin-Madison, Madison, WI, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Public policy analysis seeks to promote social values by informing participants in the policy-making process. It typically involves framing problems as inefficiencies resulting from market and government failures or undesirable distributions of opportunities or outcomes. In its most general mode, multi-goal analysis, analysts identify and justify relevant substantive and instrumental goals, specify policy alternatives, and systematically compare alternatives in terms of goals to support a recommendation. Depending on the relevant goals and the capacity for analysts to quantify and monetize progress toward goals, policy analysis may be performed in the mode of cost–benefit or cost–effectiveness analysis.

Introduction: What Is Policy Analysis?

Government officials, whether pharaohs, kings, presidents, prime ministers, legislators, or bureaucrats, face decisions that create public policies affecting the security of their states as well as the economic, social, and political lives of those who reside in them. Many of these officials, especially in routine circumstances, act as their own policy analysts, identifying alternative courses of action and predicting the consequences of these alternatives. However, even in ancient times, they sought advice from analysts. Joseph in Genesis, probably the first noted policy analyst in the Western tradition, defined the problem suggested by Pharaoh's dreams as the risk of famine following years of plenty. He recommended the policy of stockpiling grain, and accurately predicted that this policy would benefit both the Pharaoh and his people. History records individuals in India and China playing similar roles in ancient times (Goldhamer, 1978; Radin, 2013, p. 13). Today, public policy analysts, whether identified by formal title or their actual practice, can be found in almost all government agencies, think tanks, interest groups, and consultancies.

Public policy analysts are those who do *public* policy analysis. Weimer and Vining (2011, p. 24) define public policy analysis as "client oriented advice relevant to public decisions and informed by social values." In this definition, the focus on public decisions, that is, those made through the exercise of the formal authority of the state, distinguishes public policy analysis from the analyses conducted to support private sector activity, such as marketing decisions by firms. The requirement that the analysis be informed by social values distinguishes those analysts who seek to contribute to better public policy from society's perspective from those who aim to advance a particular private interest (even though these advocates typically couch their analysis as being in the public interest). So, for example, a private sector analyst who considered only maximization of profit or a political analyst who considered only their client's electoral advantage would not be conducting public policy analysis under this definition. Finally, this definition emphasizes the requirement that there be a client. This emphasis distinguishes public policy analysis as a *professional* activity – public officials who do their own policy analysis can be thought of as having themselves as a client. This aspect of the definition may be the most controversial component because it clearly distinguishes public policy analysis from the broader field of policy-relevant research.

Many academics, especially those in the social sciences, do policy-relevant research. Yet they rarely have a specific client and their work typically seeks to add to general knowledge rather than inform a specific public policy decision. Absent a specific client, we label these activities public policy research rather than public policy analysis. As many readers of this article will be familiar, either as scholars or students, with published policy research, it is useful to consider a few of the ways in which policy research tends to differ from policy analysis (Weimer, 2009). Perhaps most importantly, policy research tends to emphasize particular aspects of policy problems and specific policy impacts rather than taking a comprehensive approach, largely because the audience for the work is mostly other researchers who value innovative techniques and models, rather than policy makers who seek advice about courses of policy action. Consequently, policy research tends to employ the methods of a single discipline (most frequently economics, political science, or sociology) rather than draw on multiple disciplines as is often needed to make a holistic assessment of impacts. It also reflects a timeframe dictated by the demands of the methodology employed rather than the demands of a specific decision. Nonetheless, although policy research and policy analysis differ in important ways, policy research is often an extremely valuable resource for policy analysis. Indeed, the weight of policy research related to a policy-relevant issue almost always plays an important evidentiary role in policy analysis.

The first row of **Table 1** summarizes the contrast between public policy analysis and public policy research. The second row shows a similar distinction between stakeholder analysis, which is conducted from the perspective of a specific client, and policy process research, which speaks primarily to scholars. As political feasibility and successful implementation are almost always relevant goals in public policy analysis, good public policy analysis usually goes beyond the narrow definition based on substantive goals (northwest cell) to include process analysis as well (southwest cell).

Having placed policy analysis in a broader policy context, in the rest of this article we seek to sketch the various modes of

Table 1 Policy analysis in perspective

		Client versus societal focus	
		Client focus	*Academic/societal focus*
Substantive versus process focus	**Substantive policy focus**	**Policy analysis (narrowly defined)** Problem-solving focus Economics pre-eminent Comprehensive: problem analysis (market & government failure, synthesis, solution analysis (alternatives, goals, assessment)) Goals clear, or at least emergently clear; efficiency (cost–benefit) or efficiency, equity, government revenue-expenditure (multi-goal)	**Policy research/policy sciences** Social science research on policy problems Policy problem discovery/exploration Solution (policy) discovery/exploration Broad range of social sciences, but economics, political science dominate Partial or fragmentary (in terms of policy problem) Goals contestable
	Policy process focus	**Political/organizational analysis (or stakeholder analysis)** Political, organizational, and inter-organizational analysis (including networks) Relevant for both adoption and implementation Strategic client focus Often informal and unwritten Primarily descriptive and predictive, rather than normative: goal is adoption and implementation	**Policy process research** All social science research, but dominated by political science Distributional and redistributional focus Theory somewhat contestable: interest group theory, advocacy coalition, path dependency, etc., but converging on contingent and comprehensive theory

public policy analysis, which we henceforth refer to as just policy analysis. However, as the appropriateness of the various modes depends on the nature of the goals relevant to policy choice, we first consider framing public policy problems in terms of the inefficiency resulting from market and government failures or as undesirable distributions of outcomes or opportunities.

Framing Public Policy Problems

Analysts often begin their work by being confronted with what clients or they themselves view as undesirable social, economic, or political conditions. The first task of an analyst is to understand these conditions: Has the condition gotten better, worse, or remained the same over time? Is the condition better, worse, or the same in this jurisdiction than in another comparable one? Why do or should we care about the condition? The second task of the analyst involves determining if the condition is amenable to public policy – if one can imagine changes in policy that would make the conditions less undesirable, then it becomes a public policy problem (Dery, 1984).

It is often helpful to frame problems as the inefficient use of resources because of market and government failures (Weimer and Vining, 2011). Inefficiency can arise in two ways. First, technical inefficiency occurs when some output could be produced at a lower opportunity cost. That is, some alternative mix of resources that could produce the same level of output has a lower value in its next best alternative use so that less would have to be given up to obtain the output. Second, allocative inefficiency occurs when some alternative set of outputs would be valued more by society. That is, there is an alternative allocation for which the difference between what people would be willing to pay in aggregate for it and its opportunity cost is greater than for the current allocation. So, for example, a municipal refuse system would be technically inefficient if it were possible to provide the same levels of refuse collection at a lower cost, such as by using trucks with robotic arms that reduced injuries to workers. It would be allocatively inefficient if residents valued more frequent pickup even taking account of the higher taxes they would pay to fund the additional service.

In an ideal competitive economy, individuals pursuing their own interests would efficiently use resources to achieve both technical and allocative efficiency. In a real economy, however, some circumstances, called market failures, prevent private activity from resulting in an efficient allocation of resources. The commonly recognized market failures include externalities (marginal private cost differs from marginal social cost so that individuals produce or consume too much or too little), natural monopoly (average cost declines over the relevant rage of demand so that only one firm can profitably survive in the market), public goods (nonrivalry of consumption, non-excludability of use, or both result in too little voluntary supply or too much consumption), and information asymmetries (one party to a transaction has information that, if revealed, would lead the other party to make a different decision so that either too little or too much is consumed). Additionally, various other limitations to market economies, such as imperfect insurance and capital markets, or incoherent individual choice, such as that resulting from imperfect cognition or addiction, can also result in private actions failing to achieve efficient allocations of resources. Correcting market failures to increase efficiency is one of the rationales for public intervention in markets.

Just as private actions can fail to produce an efficient allocation of resources, collective action can fail to correct market failures appropriately or actually create inefficiencies (Glazer and Rothenberg, 2001; Weimer and Vining, 2011; Wolf, 1979). Most fundamentally, no social choice rule can guarantee translation of individual preferences into a fair and coherent social

ordering (Arrow, 1951). Representative governments often give greater voice to concentrated and organized interests, sometimes creating inefficient policies that favor these interests. Problems of bureaucratic supply make it difficult for governments to use resources efficiently in the things that it directly produces. Decentralization of authority, often desirable to account for differences in geographic preferences, can nonetheless create incentives for subnational governments to adopt inefficient policies in their pursuit of fiscal advantage.

If efficiency were the only goal of public policy, then whether or not a policy problem involved a market or government failure would guide the appropriate policy response (Weimer and Vining, 2006, p. 28–31). If there is neither market nor government failure, then the market is working and should be left alone. If there is market failure and no government failure, then policy is appropriately corrective and should be left alone. However, if there is no market failure, but government failure has manifested, then a return to the market, such as through deregulation, is warranted. If a combination of market and government failure occurs, then current policy is inappropriate and should be redesigned.

Although efficiency is usually one appropriate goal of public policy, it is rarely the only one. Most often, some form of equity is relevant, whether creating greater opportunity for those with limited resources to participate in markets and civic life, providing floors on consumption to preserve human dignity, or creating a more equal distribution of consumption. Distributional goals seek greater equity in some relevant dimension.

More generally, policy analysis typically addresses multiple goals. These include substantive goals (the northwest cell of Table 1), those things analysts argue are desirable for society and often instrumental goals (the southwest cell), such as political feasibility, which are necessary for policies to realize substantive goals.

Policy Analysis Modes

The appropriate mode of policy analysis depends on answers to two questions (Vining and Boardman, 2006). First, how many distinct goals are relevant to policy choice? The framing of policy problems as market and government failures directly raises efficiency as a commonly relevant goal. Sometimes, it is the only goal. More often it is one of several substantive or instrumental goals. Whether efficiency is the only goal, one of two substantive goals, or one among many goals helps determine the appropriate mode of analysis. Second, to what extent can progress toward goals be quantified or monetized? The answer depends on both conceptual and practical considerations. Quantifying and monetizing all the relevant efficiency impacts of a policy may be conceptually possible, but not practical in terms of the data and time available to analysts. Or, although efficiency impacts can be quantified, analysts may not have sufficient information or willingness to monetize them. If a goal, such as efficiency, involves multiple impacts, then an inability or unwillingness to quantify the impacts in a common metric requires analysts to replace the single goal with multiple impact categories, effectively increasing the number of criteria across which alternatives must be compared.

Multi-Goal Analysis

The most general mode of policy analysis, multi-goal analysis, allows for multiple goals to be used to assess current policy and alternatives to it (Bardach, 2012; MacRae and Whittington, 1997; Weimer and Vining, 2011). It is always appropriate when there are more than two goals. If there are two goals, then multi-goal analysis is the most appropriate method if either one cannot be quantified. Multi-goal may even be appropriate if there is one goal, but it has multiple dimensions, one or more of which cannot be quantified. Herfindahl and Kneese (1974, p. 223) make the case that it is the only appropriate approach in some circumstances: "a final approach is that of viewing the various possible objectives of public policy as being substantially incommensurable on any simple scale and therefore necessitating the generation of various kinds of information, not summable into a single number, as the basis for political decision." (Also see Dodgson et al., 2001; Hrudey et al., 2001.)

Multi-goal analysis requires the analyst to complete a number of tasks. First, the analyst must identify and justify the selection of relevant goals. Second, identify impact categories for each of the goals. Third, specify alternatives to current policy. Fourth, systematically compare each alternative in terms of each of the impact categories. Fifth, recommend one of the policy alternatives, possibly current policy, based on the comparison.

Identify and Justify Goals

Goals encompass what analysts believe society should want from good public policy. As the assessment of alternative policies will depend on the selected goals, it is important that the goals be comprehensive and appropriate. As the enumeration of goals is an intermediate product of the analysis, the analyst should explain the rationale for the inclusion of a goal or goals and for the exclusion of other plausible goals.

A strong case can be made that efficiency should always be considered as one of the relevant goals in public policy analysis (Vining and Weimer, 2005). Thoughtful people would almost certainly agree that scarce resources should be used as efficiently as possible. Moving beyond efficiency, however, requires substantive knowledge of the specific policy area and the likely consequences of policy alternatives. Although little can be said in the abstract about what other goals to include in an analysis, there is one clear rule: Every valued impact of the policy alternatives must be taken into account under one of the goals. If an impact falls outside of the initially identified goals, then it is necessary to add an additional goal to take account of it. One implication of this rule is that changes in the set of alternatives may require a chance in the identified goals. Of course, if all the policy alternatives have the same impact relevant to a goal, then the goal is redundant with respect to comparison and should be eliminated.

In many policy contexts, equity is also an appropriate policy goal (Farrow, 2011; Myers, 2002; Rosen, 1975; Stone, 2012; Vining and Weimer, 2009). Indeed, equity has been codified in US federal regulatory practice as a goal. The United Kingdom *Green Book* (H.M. Treasury, 2003) also explicitly requires that equity be considered (and quantified) 'as much as possible' in assessing policy alternatives. The *Green*

Book suggests that equity not only be assessed for different income groups, but also for different age, gender, health status, and ethnic groups as well as by location. It is important to note that while efficiency and equity often involve a trade-off (increments of efficiency come at the expense of increments of equity), this is not always the case, especially in social policy arenas (for a further discussion of this, see Vining and Weimer, 2009, p. 2–4).

Apart from the goals of efficiency and equity, there is a legitimate instrumental reason to include the (net) impact on government revenue of policy alternatives as a policy goal, or sometimes as a constraint, frequently labeled 'revenue–expenditure impact.' The two major US (federal) policy analysis agencies, the Government Accountability Office and the Congressional Budget Office, posit three goals in most of their analyses: efficiency, equity, and impact on government revenues. An important rationale for the inclusion of revenue–expenditure impact for many governmental entities performing policy analysis is that they have effectively fixed budgets. Although other levels of governments may have the power to increase revenues through additional taxing, many subnational governments are constitutionally not permitted to run deficits. Thus, the impact of policies on government expenditures is often of crucial practical concern.

Ethical concerns often suggest other goals (Adler and Posner, 1999). For example, some argue that public policy should promote virtues, such as altruism or humane treatment of animals, not because of any social value they produce but rather because they are intrinsically desirable. Others argue for goals based on the value of preserving the natural environment, which might go beyond facilitating human use of the environment or even ecological goals such as maximizing the number of surviving species.

Finally, and most controversially, analysts have to consider whether to include political feasibility as a goal (or, again, at least as a constraint). The argument that political feasibility is an appropriate goal recognizes the reality that all major public policy decisions require the approval of political actors (Webber, 1986). Most policy analysts must take this reality into account in choosing among policy alternatives. However, analysts may sometimes ignore immediate political feasibility to initiate dialogue about an alternative that may become politically feasible in the future.

Specification of Impact Categories

Creating a comprehensive scorecard for comparing alternatives often requires analysts to specify impact categories for assessing progress toward multidimensional goals. For example, efficiency in the context of a public health problem may involve mortality, morbidity, and use of medical resources. If all three could be monetized, then their sum would incorporate all three impacts in a single efficiency measure. However, if mortality and morbidity cannot be monetized with available resources, then the goal of efficiency would require three impact categories for assessing alternatives.

Multiple impact categories can be required for other goals as well. For example, consider the goal of equal opportunity for political participation. Policies can have differential impacts on low-income groups and ethnic minorities. Even an instrumental goal, like political feasibility, may require multiple impact categories. For example, the analyst may believe that both public acceptability and impact on organized interest groups are relevant to the political feasibility of policy alternatives, but not have enough knowledge to assess their relative importance in making an overall prediction.

Specification of Policy Alternatives

The analyst begins with at least one policy alternative: current policy. Nonetheless, specifying current policy requires an explicit effort to identify the laws, norms, practices, procedures, and constitutional provisions that are relevant to the policy problem. The analyst must then develop and fully specify alternatives to current policy. An alternative is fully specified when its elements are defined in sufficient detail to allow predictions of its impacts. For example, predicting the impact of a higher alcohol tax on consumption requires a specification of at least the new level of the tax and the alcohol products to which it would apply.

How do analysts identify policy alternatives? Often organizations and other advocates offer alternatives that advance their interests. Analysts may find some of these alternatives worthy of development and may choose to include others simply because they will receive attention in the political process. More generally, the analyst can borrow, tinker, forward map, or backward map (Weimer, 1993).

One strategy, especially for analysts working for subnational governments, is to borrow either adopted or proposed policies from other jurisdictions (Schneider and Ingram, 1988). In the United States, organizations such as the National Conference of State Legislatures and the National Governors Association facilitate comparison of policies across states. Once a policy alternative is identified, whether borrowed or created anew, it provide a starting point for creating new alternatives through tinkering with elements of the alternative (May, 1981). Tinkering involves identifying the basic elements of the policy, identifying possible options for replacing each element, and then constructing new alternatives by assembling viable combinations of the options. For example, one version of a recycling program might involve no requirement for the separation of the recyclables by householders, weekly pickup, and processing by a city facility. Another alternative could instead specify separation by householders of paper from other recyclables, pickup every two weeks, and processing by a contractor. Just these two variations for each of the three elements would require the analyst to analyze eight possible alternatives.

Framing policy problems as market or government failures provides alternatives through "forward mapping" (Weimer and Vining, 2011): Each of these failures has associated with it common policy responses that can be the starting point for the development of policy alternatives. For example, a framing of a policy problem as resulting from a negative externality immediately suggests either a response based on internalizing the externality either through a tax on the externality producer or through a regulatory regime that reduces the harm produced by the externality. Of course, considerable specification will be needed to convert the generic policy response into a policy alternative for which the analyst can predict impacts.

Rather than through forward mapping, analysts may also develop alternatives through "backward mapping" (Elmore, 1979–80). Backward mapping starts with behavior that policy

seeks to change, then works back through a causal change to an initial policy decision. For example, consider the problem of rising municipal refuse costs. An analyst may seek to reduce or dampen this rising cost by encouraging residents to separate yard waste from their other household waste, usually by placing it in specially marked bags. A requirement for separation and a fine for not doing so, coupled with weekly pickup during the growing season, is hypothesized to change waste disposal behavior. Working backward toward a policy requires that bags must somehow be made available to residents, say through supermarkets. Some feasible method, such as allowing supermarkets to print advertising on the bags, must be found to provide the appropriate incentives for this altered behavior. The city council must specify the bag characteristics, authorize advertising on it, and provide resources to the sanitation department for pickup and rural disposal of the yard waste, and impose the bagging requirement. Reversing the behavioral causal chain results in a policy alternative to consider, beginning with the necessary actions by the city council.

Comprehensive Comparison

Comparing policy alternatives requires that the impacts of each policy be assessed in terms of each of the goals (or its impact categories). Analysts often find that the construction of a goals/alternatives matrix facilitates this comparison and its communication to clients. Typically, the rows of a matrix are labeled with goals (and impact categories) and the columns by policy alternatives. The cells then contain the predicted impacts of the policies. Analytic comprehensiveness requires that predictions be placed in all cells. The goals/alternatives matrix facilitates the identification of the various trade-offs among the identified alternatives in terms of achievement of the goals. Although it is possible to develop point systems or other criteria for providing summary assessments of alternatives (Davey et al., 1994), these approaches tend to be arbitrary and often obscure trade-offs. Therefore, they should be used with caution.

Making a Policy Recommendation

The final step in a comprehensive multi-goal analysis requires the analyst to make an explicit argument in favor of the alternative being recommended. This argument addresses the various trade-offs identified in the comparison. Clear and transparent arguments increase the chances that clients will benefit from the analysis even if they reject the recommended alternative. Notably, some government agencies (such as the CBO) do not include this final step.

Efficiency Analysis

When efficiency is the only goal, or one of two goals, analysts may be able to employ one of two particularly valuable analytical modes: cost–benefit analysis and cost–effectiveness analysis. Cost–benefit analysis is feasible and desirable when efficiency is the only goal and all impacts of alternatives relevant to efficiency can be monetized. Cost–effectiveness analysis is feasible and desirable when either (1) all but one efficiency impact can be monetized and the remaining efficiency impacts can be quantified or (2) all efficiency impacts can be monetized and the only other (non-efficiency) goal can be quantified.

Cost–Benefit Analysis

Cost–benefit analysis seeks to assess efficiency by aggregating all valued impacts of policy alternatives relative to current policy (Boardman et al., 2011; Farrow and Zerbe, 2013; Vining and Weimer, 2009). The guiding principle for monetizing impacts is the willingness of those affected to pay to obtain or avoid the impacts. Analysts have developed a variety of methods for predicting willingness to pay, ranging from drawing on preferences revealed by observable behavior in markets at one extreme to preferences about public goods elicited from surveys of relevant populations at the other. These methods allow analysts to estimate the net benefits of proposed policies relative to current policy. Among all the policies with positive net benefits, the set with the largest net benefits maximizes efficiency.

The history of the use of cost–benefit analysis in the United States begins with federal legislation supporting harbor, canal, and other infrastructure development at the turn of the twentieth century that required the Army Corps of Engineers to assess the costs and benefits of proposed projects (Hammond, 1966). Subsequently, efforts by environmental economists to apply it to natural resource projects led to the development of 'stated preference' and other methods that have since been employed in other policy areas. However, the greatest impetus for the actual use of cost–benefit analysis was President Reagan's Executive Order 12291 calling for Regulatory Impact Analyses, which require agencies to conduct cost–benefit analyses of proposed regulations that would have an effect on the economy of more than $100 million annually. Subsequent executive orders by Presidents Clinton and Obama extended the proposed rules subject to such analysis and required agencies to conduct retrospective analyses of already adopted rules. Although some states have adopted requirements for the application of cost–benefit analysis to specific policy proposals, such as proposed regulations or insurance mandates, there has been less routine application of cost–benefit analysis at the subnational government level. A major exception is the cost–benefit model developed by the Washington State Institute for Public Policy, which has been adopted in a number of other states with foundation support (Pew Charitable Trusts and MacArthur Foundation, 2014).

Cost–benefit analysis is seeing increased use in other countries as well. For example, the United Kingdom has recently increased emphasis on monetization for project appraisal and now requires "Wherever feasible, attributing monetary values to all impacts of any proposed policy, project and programme…" (H.M. Treasury, 2003). As economists and other researchers find ways to estimate "shadow prices," or imputed per unit social values, for various policy impacts, the feasibility of monetization will increase, as will the range of policies for which cost–benefit analysis is possible (Vining and Weimer, 2010).

Cost–benefit analysis serves as an appropriate decision rule only if efficiency is the only goal – a condition that is very rare in addressing major policy problems. However, it can also be viewed more generally as a protocol for assessing efficiency. Thus, cost–benefit analysis can be "embedded" within a multi-goal analysis in which efficiency is one of the goals (Vining and Boardman, 2006). Indeed, this is the role that

cost–benefit analysis actually plays in Regulatory Impact Analyses and in almost all other applications.

Cost–Effectiveness Analysis

When efficiency is the only goal, the ideal application of cost–benefit analysis requires that all impacts affecting efficiency be monetized. However, if one of the impacts can be quantified, but analysts are unable or unwilling to monetize it, then cost–effectiveness analysis may be helpful in identifying relatively efficient policies. For example, although there is a large and reasonably consistent literature on people's monetized willingness to pay for reductions in mortality risk (Viscusi and Aldy, 2003), many health policy analysts decline to apply this willingness to pay to monetize mortality reductions.

Cost–effectiveness analysis involves estimating the net incremental cost and net incremental effectiveness in moving from a reference policy to an alternative. For example, a program to increase vaccinations through a new public service announcement would estimate incremental cost as the cost of the new program and incremental benefit as the predicted number of additional vaccinations. A cost–effectiveness ratio for this program would be the ratio of the incremental cost to the incremental benefit.

It is important to note that cost–effectiveness ratios do not necessarily identify the most efficient program. Only if either all alternatives have the same incremental cost or all alternatives have the same incremental effectiveness does the cost-effectiveness ratio provide an unambiguous basis for ranking programs in terms of efficiency. The latter often holds in defense analyses in which military planners decide on some level of effectiveness, such as the "number of tons of supplies that can be delivered to a conflict theater in a certain time," and alternatives for achieving it are compared in terms of cost. In the more common situation in which both incremental costs and incremental effectiveness vary across alternatives, the relative efficiency depends on the shadow price applied to effectiveness – a value the analyst is apparently unwilling to specify. Further, comparison of cost–effectiveness ratios can be misleading if analysts fail to remove dominated alternatives, those alternatives with either the same effectiveness but higher cost or the same cost but lower effectiveness than other alternatives (Gerber, 2000). Consequently, considerable care must be taken by analysts in using cost-effectiveness to assess efficiency.

Cost–effectiveness may also be applied when all efficiency impacts can be monetized and there is one additional goal that can be quantified. For example, policies that would reduce the number of families living in poverty, a distributional goal, might involve different net social costs. These policies might be assessed in terms of net social costs per family removed from poverty. However, all the caveats that apply to the use of cost–effectiveness ratios in the case of a single goal of efficiency apply in this extended application as well.

Incomplete Analyses

Several commonly employed modes of analysis, although typically incomplete in their own right, are often of some value in developing an effective multi-goal analysis. Probably the most important of these in practice are fiscal analysis, stakeholder analysis, and program evaluation.

Fiscal Analysis

Many legislatures require analysts in supporting organizations to assess the fiscal impacts of proposed policies (essentially revenue–expenditure analysis). Simple analyses consider fiscal impacts only in the current fiscal year; more sophisticated analyses predict fiscal impacts over a longer time horizon. Sometimes fiscal analyses, such as those done by analysts for specific agencies, are even less connected to valued outcomes because they limit attention to budgetary implications for only that agency. In any event, unlike cost–benefit analysis, fiscal analysis counts only government revenues as benefits and only government revenues as costs. Consequently, net fiscal impact is not a measure of efficiency. Nonetheless, net fiscal impact is often a relevant instrumental goal in multi-goal analysis so that a well-done fiscal analysis may be a valuable component of a more comprehensive analysis.

Stakeholder Analysis

Various stakeholders, individuals, groups, and organizations, affect policy choice. Stakeholder analysis assesses the prospects for policy change by considering "the position, interest, influence, interrelations, networks, and other characteristics of stakeholders" in the past, present, and future (Brugha and Varvasovsky, 2000, p. 239). Its primary focus is predictive rather than normative. Nonetheless, stakeholder analysis may be useful in helping analysts predict political feasibility, a common instrumental goal in multi-goal analyses. Stakeholder analysis is also often useful in assessing the likelihood of successful implementation and adjusting policy designs to increase it. Implementation can be thought of as an assembly process where various stakeholders control the essential elements (Bardach, 1977). Understanding the interests and resources of these stakeholders helps analysts anticipate the extent to which they will cooperate in providing essential elements as well as strategies for increasing cooperation or getting along without it when it cannot be secured.

Program (Policy) Evaluation

Sometimes policy analysts, but more often policy researchers, assess the impacts that have been produced by some policy, commonly a program that employs some resources to achieve some policy goal. Although the assessments often cannot go beyond description, sometimes the evaluations of policies to help individuals are planned so that potential participants can be randomized into treatment (in program) and a control (not in program) or groups facilitating an assessment of causality – the likelihood that the program produced the observed outcomes. Absent such randomization, researchers must be clever in identifying valid comparison groups and employing statistical methods to assess causality (Langbein, 2012).

Program evaluation is retrospective. It becomes policy analysis when it is used prospectively to inform decisions about continuation, expansion, reduction, or termination of the evaluated program. It may also inform decisions about replicating or terminating similar programs, especially if it is one of many evaluations whose findings can be combined in a meta-analysis

(Lipsey and Wilson, 2001). Unfortunately, program evaluation done by policy researchers often fails to be comprehensive in its assessment of impacts, often focusing narrowly on the primary program goal and typically ignoring costs or even a systematic catalog of the required resources needed to implement the program. Thus, although it can be extremely valuable in helping analysts predict some of the program impacts, it often requires analysts to gather additional information to support policy decisions.

The Use of Policy Analysis

The primary focus of this article has been on the normative value of policy analysis. Thus far, it has not addressed the question: How widely is policy analysis actually used in policy making? One thing is clear, its direct impact is not clear! As Nilsson et al. (2008, p. 335) emphasize, "three decades of policy-analytic research reminds us that the inter-relationship between assessment tools, the evidence they reveal, and their use by policy makers is unlikely to be straightforward." (See also Weiss, 1979; Shulock, 1999; Radaelli, 2004; Howlett and Lindquist, 2007.) Additionally, the use and the directness of use of formal policy analysis vary widely across countries and jurisdictions. However, it is certainly the case that most developed countries have expanded their production of analysis over the last two decades.

In the United States, Whiteman (1995, p. 181) concludes, based on a study of communication surrounding four policy issues in the areas of health and transportation before the US Congress, that: "The results ... indicate that policy analysis clearly does flow through congressional communication networks. In three of the four issues examined, analytic information played a significant role in congressional deliberations." Almost certainly, these analyses have influenced members of Congress and their voting.

The most important use of policy analysis by the US federal government, however, is in the federal regulatory arena because of a series of Presidential executive orders requiring it (see Vining and Weimer, 2014). These executive orders routinely require the use of cost–benefit analysis (or something close to it) to assess new rules proposed by regulatory agencies as well as to review state and local government proposals for federally supported infrastructure projects. Although this oversight of the rulemaking process may appear somewhat narrow, it is important to recognize that much of the content of federal policy is set through rulemaking and that some of the proposed regulations would provide benefits and impose costs that amount to billions of dollars.

Legislatively, an important milestone was the passage of the Treasury and General Government Appropriations Act (P.L. 106-554). This Act requires the Office of Management and Budget (OMB) to report annually to Congress on the benefits and costs of federal regulations. The 2012 report documents that, during the first 10 years of reporting, 103 rules were both economically significant and featured cost–benefit analyses that monetized substantial portions of the reported benefits and costs (OMB, 2012).

At the state level in the United States, the use of policy analysis is highly variable. The impact of policy analysis – specifically cost–benefit analysis and cost–effectiveness analysis – appears to be significant in some states, such as Washington (Vining and Weimer, 2014).

Nilsson et al. (2008, p. 352) provide evidence that policy analysis does get used in the European Union countries (and the Union itself) but that, not surprisingly, "tools are likely to be selected primarily on the basis of organizational routines and standard practices and on the expectation that they will produce evidence that speaks directly to, and supports, the core beliefs of governing coalitions…to ensure that the evidence gathered buttress core interests."

Conclusion

Policy analysis in representative government can play a valuable role in specifying and predicting the consequences of alternative policies. In doing so, it can also address those interests in society that lack adequate articulation or representation in the arenas of collective choice. Efficiency is such an interest. However, because of the nature of collective choice, governments, especially representative governments, face tremendous pressures to adopt inefficient policies. Especially when viewed over a range of policies and over time, greater allocative efficiency almost always diffuses to benefit almost all members of society. At the same time, however, as stakeholder analysis nearly always highlights, almost all proposed policies have distributional consequences and the political process in representative government tends to favor policies that provide benefits for organized interests and impose costs on unorganized interests. Policy analysis, as we have defined it, can help counteract this pressure. But policy tools, as with other tools, are only as useful as the intentions of those wielding them. Some progress has been made, but much more can be done (Anthoff and Hahn, 2010).

Policy Analysis: Evidence Based Policy-Making

Brian W Head, The University of Queensland, St Lucia, QLD, Australia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Systematic use of rigorous evidence in the policy process is widely expected to produce more accurate policy advice. However, these scientific aspirations will always be limited by democratic political debates, stakeholder lobbying, and popular opinion. Policy analysts in government agencies attempt to utilize research and evaluation evidence relevant to the feasibility and effectiveness of current and proposed service programs and regulatory regimes. But their capacity to provide policy advice enriched by 'evidence-based' analysis is dependent on the availability of reliable socioeconomic data, use of advanced analytical techniques, investment in program evaluations, and support for transparent policy processes by administrative and political elites.

Introduction

There is a widely supported principle that public policy making should be based on the best available knowledge concerning the issues under consideration. In recent decades, the concept of 'evidence-based policy' has been more precisely elaborated and advocated. The essential meaning of the term is that objective knowledge from scientific research including rigorous evaluation studies should occupy a central place in policy decision making. Seeking rigorous and reliable knowledge and promoting its utilization within the policy process are core features of an evidence-based policy approach. Considerable efforts have been made in many countries to invest in the systematic data, the analytical skills, and the decision processes that would provide better foundations for a more evidence-informed approach. Evidence-based policy is an attractive concept for professionals concerned with building robust information bases and improving the techniques for analysis and evaluation. Nevertheless, alternative decision-making principles and practices – based on appeals to policy precedents, leaders' authority, or political self-interest – have been much more prevalent in most countries at most periods in time.

Historical Development and Overview

Over the last two centuries, there has emerged a growing conviction that reliable empirical knowledge, based on systematic analysis of evidence, could become a powerful instrument in providing more accurate and effective advice to governmental leaders. The scientific-technical thrust of this doctrine was initially directed toward the more efficient governance of nation-states in their quest to create industrial and commercial wealth. Technological sciences generated improvements in transportation, military capability, energy and water systems, and infrastructure for the growth of cities. In addition, epidemiological studies facilitated breakthroughs in public health, such as sanitation systems and control of communicable diseases. Since the 1920s, and especially since the 1950s, the empirical social sciences – such as sociology, economics, political science, social psychology – have opened up new dimensions and new tensions in the relationships between science and policy making. Historically, the enlightenment ethos has provided the normative underpinning of both the technological and social sciences, namely, the belief that scientific understanding of social and natural forces can generate economic wealth and social progress.

In advanced Western nations, the social sciences developed rapidly in the 1940s and 1950s, exemplified by Keynesian economics and welfare-oriented social and educational planning. In the United States, the 'policy sciences' championed by Lasswell and colleagues were clearly linked to the value bases of social progress and democracy (Lerner and Lasswell, 1951). Social scientists became deeply involved in the ambitious public programs addressing social welfare, educational reform, urban renewal, and race relations in North America, Europe, and Australasia over several decades from the 1960s and beyond. However, the results were often disappointing, and some of the blame fell on the inadequacies of social research, as well as the poor coordination and implementation capacities of government agencies.

How could the social sciences become more precise, reliable, and thus useful? By the 1970s, a growing group of leading social scientists were advocating the importance of rigorous behavioral and experimental methods, insisting that the social sciences should raise their 'scientific' standards as a basis for providing more accurate and trustworthy advice. Analysis of quantitative data derived from social experiments was strongly advocated as a means of providing more precise and reliable evidence for decision makers (e.g., Campbell, 1969). This focus on advocating the potential benefits of greater rigor and the use of advanced analytical methods, generated support in some government agencies, research centers, and research funding bodies, especially in the United States (Radin, 2000). A significant professional grouping of policy analysts and program evaluators developed, in step with the growing influence of the 'evidence-based' policy movement.

The UK central government, under Prime Minister Blair from 1997, attempted to develop a more coherent approach to policy development, championing evidence-based policy as a major element in developing the fresh thinking and increased policy capability that would be required by a reformist government (UK Cabinet Office, 1999; UK Treasury, 2007).

This approach became institutionalized through new public service units and cross-departmental teams working on complex issues. It was also reflected in initiatives for skills development and training for public servants and evaluators. Importantly, the UK Economic and Social Research Council (ESRC) also committed substantial funds to broad long-term research programs on evidence-based policy and practice, thereby linking the spheres of policy making, evaluation research, and improved professional practice in health, education, and social care. Issues targeted by the ESRC included the barriers and facilitators to research utilization, and programs to build techniques and capacities for evidence-based policy and professional practice. The diverse findings of these research programs have played a crucial role in legitimating rigorous approaches to applied research (Nutley et al., 2007). Moreover, international agencies, such as the Organization for Economic Cooperation and Development (OECD, 2010), have also been strong advocates for taking evidence-based approaches to policy development, innovation, and regulatory reform; while the European Commission and several agencies responsible for international development aid have also taken a strong interest in the effectiveness of funded programs.

The demand for rigorous social and economic research stems largely from government agencies gathering information on program outcomes, and from legislative committees that oversight the effectiveness of agency performance. In the United States, several state legislatures and Congressional committees have developed requirements for evidence-based justification for many social welfare programs. The federal Office of Management and Budget has repeatedly warned that evidence of cost-effectiveness is crucial for federal funding of programs, and this is all the more important in times of fiscal austerity. Government agencies and legislative bodies draw on diverse external bodies for expert information and advice, but there is also substantial capacity inside the public sector for gathering and processing social and economic information for the policy process. In federal nations (such as Germany, Canada, and the United States), policy analysis and evaluation capacity is required at both national and subnational levels, leading to some challenging problems of coordination and even competition in some public policy areas.

Evidence-based policy has become a catchcry in recent decades in those countries (especially in the OECD group) that take seriously the quality of policy analysis and the evaluation of program effectiveness. Where the political culture allows substantial elements of transparency and rationality in the policy process, decision makers are more likely to support increased utilization of policy-relevant knowledge. Supportive research cultures encourage and foster a commitment to rigorous methodologies for generating a range of policy-relevant evidence and analysis. Evidence-based policy has been a growth area in policy research because of these demand and supply factors: the needs of government decision makers for certain types of information about problems, programs and the effectiveness of options, and the increased supply of tools and techniques for analysis and evaluation of policy that emerged over recent years. The policy areas most committed to the principles of evidence-based policy are medical and health programs, technology and innovation policy, economic growth and stabilization, environment and natural resource management, education and training, social welfare, and criminal justice. But in all these areas, there are strong stakeholder views and vested interests that constrain and reshape the ways in which problems are framed and solutions proposed.

The reputation of clinical medicine in pioneering 'evidence-based' approaches remains very powerful. Thus, much of the literature on 'evidence-based' social evaluation begins by asking whether rigorous health-based methods are fully applicable to other areas of policy, such as social welfare, schooling, juvenile justice, and community health. While much of this literature concludes that the uptake of 'evidence-based' approaches is warranted, it is also noted that there are significant variations across policy domains in relation to how policies should be assessed and modified in the light of better information (Nutley et al., 2007; Bochel and Duncan, 2007).

Alongside the focus on using evidence for improving public policy decision making, the concept of 'evidence-based practice' has also been widely adopted, especially in health and social care. For example, major efforts have been made to 'translate' the findings and lessons of health research into clinical guidelines to be used by health care professionals (see, for example, the UK Web site http://www.nice.org.uk). Closely connected to this 'translational' research, the associated fields of 'implementation' research are concerned with how scientific findings can be fruitfully translated into a wide range of complex organizational contexts and professional settings, and how program evaluations can be used to improve policy and practice (see, for example, the journal *Implementation Science* and the Web site of the Coalition for Evidence-Based Policy http://coalition4evidence.org). However, the challenge of extracting 'lessons' from research findings and adopting them successfully in professional practice entails complex issues of interpretation, education, relationships, and collaboration across professional boundaries.

Forms of Evidence for Policy

The quest for evidence-based policy involves carefully using the findings of rigorous research to improve the quality of public policy making and program review. The availability of solid evidence may also better inform policy debates in the wider community. Good-quality research is intended to improve the accuracy of advice concerning the efficiency and effectiveness of policy settings and future alternative options. To underpin the scientific character of data analysis and its translation into policy advice, a substantial guidance literature considers methodological questions concerning data validity and analytical reliability. Specialists in the design of data collection and statistical analysis are crucial for ensuring the quality of information used in applied research on specific problems. Clearly, there are many kinds of relevant data, and many sources of evidence. For researchers and evaluators, a range of methods is available for analyzing information and for interpreting research and evaluation findings (Davies, 2012).

Perspectives on Evidence Reliability

In areas of knowledge uncertainty and policy debate, the quality and reliability of evidence should be important. The

most fiercely debated notion in 'evidence-based policy' is the claim that there is a 'hierarchy' in the reliability of research-based evidence. According to this viewpoint, the highest ranking is accorded to those findings derived from rigorous experimental methodologies, similar to those championed in medical research. This viewpoint is broadly consistent with the quantitative thrust in several social science disciplines, such as experimental criminology, or the cost-benefit analysis utilized in program evaluation. A more specific version of this argument is the claim that the findings from randomized controlled trials (RCTs) – first pioneered in health research to appraise clinical interventions – are inherently superior, with the associated claim that RCTs should be more widely used in the applied social sciences. (For advocates of RCTs, see the Web site of the Coalition for Evidence-based Policy http://coalition4evidence.org and the Web site of the Campbell Collaboration http://www.campbellcollaboration.org.)

In order to establish reliable knowledge in a policy or program area, including patterns of social causality and the effects of interventions, it is necessary to undertake 'systematic reviews' of available research, paying special attention to the findings drawn from those studies that exhibit rigorous methods (Petticrew and Roberts, 2005). According to the evidence 'hierarchy,' the very reliable comparative findings of RCTs can be contrasted with less reliable findings emerging from other research designs such as single case studies, or from interviews with experienced managers and practitioners. However, some disciplines in the social sciences (e.g., social anthropology, history, law, and political science) are critical of the high status accorded to experimental trials such as RCTs, instead assigning high importance to understanding the motives, values, and perceptions of stakeholders, service providers, and decision makers. Thus, some disciplines tend to focus on qualitative evidence about the 'lived experience' of participants – understanding in depth their attitudes, intentions, and contexts for action.

The counterarguments against the primacy attributed to RCTs are both practical and methodological. First, it is noted that the RCT measurement approach requires isolating a small number of variables within a stable social context: this is difficult to achieve in many sensitive areas of policy affecting vulnerable social groups. Moreover, it may be ethically challenging to provide benefits to some members of a vulnerable group and not to others. Second, the scientific validity of quasi-experimental results may not apply, once the pilot studies are expanded and transposed into mainstream programs that entail complex interactions with other programs and with sources of external change. Third, the advocates of RCTs necessarily downplay the field experience of professionals who have contextual knowledge of what works under what conditions (Schorr and Auspos, 2003). Studies of program implementation, including the study of how clients actually experience these programs, generally show that policy managers, funders, scientists, and service users may have different perspectives on what kinds of evidence about program outcomes are most trustworthy (Pawson, 2006). It is important to address the different levels of trust in the reliability of research findings. A key challenge is therefore how to combine the practical knowledge of service delivery professionals (and their clients) and the scientific findings emerging from quantitative studies of program outcomes.

Government agencies have generally been wary of prescribing a single preferred methodology, but have often had a preference for quantitative studies of cost-effectiveness. Providing economic cost-benefit ratios is highly attractive for decision makers, who are interested in the best return on investment. For example, James Heckman demonstrated in a series of studies that return on investment was higher for early childhood education and services than for schooling as a whole (see Heckman and Masterov, 2004); this research has influenced decision makers internationally to invest more heavily in 'early years' services especially for disadvantaged families. In the United States, which has the largest concentrations of professionals working in program assessment and analysis, the mandating of particular methodologies in program appraisal has proceeded further than in most other nations, for example, by legislatures requiring rigorous evaluation as a condition of continued program funding. Understanding complex issues and associated interventions will require methods that go beyond computer-assisted data modeling. Longitudinal panel studies have become an increasingly rich source of several types of evidence. Program evaluation professionals increasingly use a variety of methods as appropriate, building bridges across the divide between qualitative and quantitative information. Mixed methods are increasingly championed by analysts and evaluators who are attempting to explain complex problems and assess complex interventions (see Woolcock, 2009).

Types and Sources of Evidence in Policy Making

Policy decisions in the real world are not deduced from empirical-analytical models, but from politics and practical judgment. The cognitive world of decision makers comprises an interplay between facts, norms, interests, and various preferred courses of action. In the real world of policy making, what counts as 'evidence' is diverse and contestable. The policy-making process in democratic countries uses the rhetoric of rational problem solving and managerial effectiveness, but the policy process itself is fuzzy, political, and conflictual (Head, 2010). A skeptical-realist view was suggested many years ago by Charles Lindblom:

> Instead of reaching 'solutions' that can be judged by standards of rationality, policy making reaches settlements, reconciliations, adjustments and agreements that one can evaluate only inconclusively by such standards as fairness, acceptability, openness to reconsideration and responsiveness to a variety of interests. And analysis in large part is transformed from an evaluative technique into a method of exerting influence, control and power which we call partisan analysis.
>
> Lindblom, 1980: 122

Lindblom perhaps went too far in discounting the 'evidence-based' vision of social sciences that would seek to inform (if not shape) the exercise of political power. But Lindblom was correct in noting that the policy process comprises many activities in which scientific rigor rubs up against power, interests, and values. In many countries that enjoy high levels of research investment, scientific knowledge does provide an important contribution to policy making.

Such research and analysis is undertaken in many institutional contexts, whether inside government agencies, or elsewhere, such as academia, think tanks, consultancy firms, and business or community organizations. In particular, the role of rigorous evaluation has gradually become more substantial in the policy and review process of many countries, in conjunction with the increasing capability of evaluation practitioners to assess the effectiveness of complex interventions.

Thus, rigorous scientific analysis constitutes one important voice in the larger world of policy and program debate. Several other types of knowledge and expertise have legitimate voices in a democratic society. These other (nonscience) knowledge cultures include political, professional, and stakeholder knowledge:

- The political knowledge, strategies, and agenda setting of political leaders and their organizations set the 'big picture' of priorities and approaches. Political ideas mobilize values and marshal information to support political objectives and to build coalitions of support. Partisan arguments and the 'spin' of political communication may become more important than objective analyses of policy effectiveness.
- The professional knowledge of service delivery practitioners, program managers, and coordinators is vital for advising on feasibility and effectiveness. Their experience in service delivery roles, and their field experience in implementing and monitoring client services, gives them unique insights into social care, education, health care, environmental monitoring, etc. They wrestle with everyday problems of effective implementation, and develop practical understandings of what works in local contexts. Their understanding of how programs may be implemented in different settings is valuable.
- Third, the experiential knowledge of service users and stakeholders is vital for 'client-focused' service delivery. Ordinary citizens may have different perspectives from those of service providers and program designers; their views are increasingly recognized as important for program evaluation in order to ensure that services are appropriately responsive to clients' needs and choices, and that service standards are set realistically. Businesses that are subject to regulatory standards provide constant feedback about the scope and burden of regulations.

Publicly funded research has become, directly and indirectly, the most important source of social science research available for governments. The preferences of government agencies and funding bodies for certain types of research can significantly influence how research is conducted. Research organizations have improved their capacities to provide research findings on topics of interest to government agencies. Policy-relevant research capacities have been consolidated into research centers in universities, consultancy firms, private sector think tanks, and not-for-profit social welfare bodies. The topics of applied research are increasingly shaped by funders' priorities.

Factors Enhancing the Use of Evidence

Evidence-based policy requires that research and evaluation findings are effectively communicated and available to be utilized by policy and program managers. However, even where the quality of research is high, the overall level of impact or utilization by decision makers is often seen as problematic or disappointing. Thus, rigorous analysis can make an important contribution, but it needs to be articulated within other aspects of the policy process such as consultation, negotiation with stakeholders, and assessing options. The political context provides both opportunities and constraints. Only a handful of policy issues are open to rethinking by decision makers at a given point in time. Some areas of policy are tightly defined by government priorities, electoral promises, and ideological preferences. Hence, the scope for new policy thinking may be limited even when major new evidence about 'what works' becomes available. Moreover, on matters of deep controversy, research findings are very likely to be appropriated and mobilized as ammunition in partisan debate.

The general conditions for building a more evidence-informed public policy-making culture include five interrelated components. First, official statistics on socioeconomic trends and public expenditure need to be systematically collected, as a baseline investment in understanding and accountability. Second, skilled personnel are required both within government and in other organizations in order to analyze and interpret the flood of information. Third, the policy system needs strong capacity to provide performance information and to undertake rigorous analysis of policy options. Fourth, the policy system needs to develop robust processes for the evaluation and review of government programs and their impact on citizens. Finally, the policy system will benefit from an open political culture and liberal flows of knowledge and opinion.

To understand the nature and extent of research uptake in the policy process, it is convenient to follow the typology suggested by Weiss (1979). She distinguished between direct (instrumental) uses or impacts of research, which may involve the direct adoption/utilization of findings (especially when research has been tailored to address a specific issue identified by decision makers), and indirect forms of influence via research contributions that enhance understandings of social processes, e.g., through new frameworks for reconceptualizing problems or solutions. Weiss also drew attention to the political or symbolic uses of research findings, when they are taken up as weapons to be deployed in favor of preferred options and against the ideas of opponents. It might be suggested that some program areas achieve a more settled character over a period of time, where a dominant paradigm is consolidated for guiding how issues are understood and addressed. Here, evidence-based arguments to refine programs incrementally within a settled policy paradigm might be quite likely to gain traction.

Roles and Relationships

Recent research has considered the strategies available for improving the interaction between the research, policy, and professional practice sectors. Researchers who seek engagement with the policy process are generally seeking influence through a variety of roles as experts, consultants, and advisors. A report commissioned by the British Academy collected evidence on perceptions about the research/policy interface. Based on interviews with researchers, policy makers, and others, several

types of potential contributions by researchers to social policy were noted:

- acting as special government advisers;
- contributing to major national enquiries or commissions;
- raising public awareness of key problems and issues;
- providing answers to specific questions through modeling or evaluations;
- providing objective analysis of what works and what does not;
- monitoring and analyzing social trends;
- providing independent scrutiny of government initiatives and developments;
- challenging current paradigms, helping to identify new approaches, concepts, and principles (see British Academy, 2008: 20).

In practice, the relationships between research producers and policy advisors are complex and variable. It is necessary to understand the factors that facilitate or hinder flows of knowledge between these groups. Given the cultural and organizational differences between governmental and academic institutions, and the different incentives shaping performance, it is difficult to create effective and enduring forms of mutual interaction and influence between the policy sector and research sector (Nutley et al., 2007; Bogenschneider and Corbett, 2010). Some academics are wary about the possible dangers of co-option and dependency that arise from close relationships, such as writing contract-research reports. Other academics seek closer engagement, but are disappointed to find that policy makers are not open minded about the value of research critical of current orthodoxies. The British Academy report listed several reasons given by policy makers as to why they avoided or ignored certain types of external research. These included perceptions that (1) their own agencies did not highly value research and did not communicate research findings within the agency; (2) research undertaken by internal staff or by contracted consultants was more likely to be seen as relevant; (3) external academic research was not seen as timely, or not seen as relevant to users' current needs; and (4) research was less likely to be used when findings were controversial or upset the status quo (British Academy, 2008: 27).

Methods to enhance interaction need to take account of the known systemic obstacles to research-informed policy approaches. Thus, research findings that reinforce policy preferences of political leaders, and that consider carefully the political and financial feasibility of policy options, are more likely to be positively received. By contrast, rigorous research that queries the favored assumptions of political leaders will be unwelcome in some quarters and may undermine trust in the neutrality of policy research. In considering methods to promote the use of rigorous evidence, the early waves of 'science communication' emphasized the need to increase dissemination as a basis for the 'transfer' or 'transmission' of research knowledge into the policy sector. This approach is now regarded as too linear and simplistic. The challenge is to consider methods for mutual understanding and influence, such as jointly managed 'learning' processes, or creating new channels and forums for mutual understanding and influence.

A number of 'bridging' strategies have been developed in recent years to ensure that both the researchers and policy makers learn more about each other's business as a basis for better utilization of policy-relevant research. It is important here to recognize the substantial role of 'in-house' research and evaluation activities inside public agencies, as well as the findings of 'external' researchers in academic and independent bodies. The channels through which rigorous evidence might influence policy making are somewhat fragile, and therefore require specific care and attention. Supply-side provision of good research about 'what works' is not enough. Potential users of research findings will pay closer attention only if they are familiar with these potential inputs, understand the advantages and limits of the information, and are in a position to make use of the findings either directly or indirectly (Nutley et al., 2007; Ward et al., 2009). Thus, the social and institutional foundations for evidence-based policy do not emerge naturally from information systems adjacent to the policy process. Capabilities and understandings need to be built within and across organizations. If the suppliers of rigorous research and the policy community are mutually ignorant or indifferent, there is little prospect of evidence-based policy becoming more robust. This situation could be exacerbated by gaps in the technical knowledge of policy makers, but is more likely to arise from deficiencies in relationships, communication, and overlapping interests. Case-study research is beginning to demonstrate in more detail the contextual factors that influence policy choices and program effectiveness. These case-studies also draw attention to factors that may facilitate or hinder research utilization by policy makers and program professionals, and ultimately throw more light on the conditions for institutional learning (Nutley et al., 2010).

Challenges and Criticisms

The rationalist perspective aims to promote evidence-based policy making as a scientific contribution to achieving cumulative knowledge for iterative policy learning within a democratic policy process. For some countries with weak information systems, or with patronage-based political systems, this approach is seen as aspirational or unrealistic; the challenge for them is to make best use of diverse local knowledge while drawing on external expertise and continuing to build a more systematic information base for policy and performance management. Among the OECD countries, which generally have a robust information infrastructure, there are other concerns and challenges underlying attempts to build better evidence bases and strengthen the links into policy and program development.

For example, concerns have been expressed by critics who claim that evidence-based policy is inherently elitist or 'technocratic,' owing to its preference for scientific expertise and quantitative precision over other forms of knowledge. The relationships between expert technical knowledge and other forms of relevant knowledge are only weakly acknowledged by advocates of evidence-based policy making. This is unfortunate, as some of the earlier champions of progress in the social sciences (e.g., Lerner and Lasswell, 1951) recognized that democratic policy making requires community education and

strong processes for stakeholder involvement. A related concern has been the view that evidence-based approaches have become harnessed to the efficiency agendas of government rather than to the innovation and social benefit agendas. These different perspectives about rationalist policy making are grounded in different epistemologies and different views about the centrality of dialogue and participatory deliberation, and are therefore unlikely to be resolved.

A further area of concern has centered on the importance of long-term governmental commitment to improved processes for program implementation and evaluation. Ideally, the investment in evidence-based approaches would focus on important issues where research and evaluation findings could lead to better understanding of patterns, trends, and causes. In a complex policy intervention, clear program outcomes may not emerge for several years. But political leaders are often impatient for quick results, insisting that measurable outcomes be available in a short time frame. This pressure can lead to a focus on visible projects rather than on building foundations for sustainable benefits. Moreover, governments have a propensity to change a program before outcomes have been assessed, so that evaluations would be measuring moving targets.

Fortunately there are recent examples of solid commitment to program stability and to long-term evaluation. In the United Kingdom, for example, a complex program targeting early childhood development in disadvantaged communities ('Sure Start') underwent several changes to improve coordination, but the major ongoing evaluation project managed to provide an impressive series of assessments over several years (see Web site: http://www.education.gov.uk/childrenandyoungpeople/earlylearningandchildcare/evidence). Another area of major investment in policy-relevant research, in the United States and elsewhere, is the ongoing evaluation of 'welfare-to-work' programs, whereby parents in disadvantaged households are strongly encouraged to develop workforce experience and skills (e.g., Haskins, 2006).

A third challenge is how evidence-based approaches can deal with large and complex problems, rather than the simpler issues for which the variables can be specified and controlled. Experimental evaluations like RCTs work best in relatively simple environments. In complex programs with multiple objectives, such as antipoverty interventions where the clients are subjected to many sources of influence beyond the scope of the program, the challenges of accurate understanding are compounded. Moreover, many factors influence how these policy problems are framed, debated, researched, and managed. This diversity poses diverse challenges for evidence, analysis, and recommendation. The political requirement for solutions will sometimes encourage rapid generic responses, rather than the long pathway of detailed field research with careful evaluation of experience across a range of localities. Complex social problems (such as gun control, refugee resettlement, and juvenile justice) are often characterized by underlying clashes of values, which need to be handled politically rather than through larger amounts of scientific information. Conflict mediation, stakeholder coordination and provision of incentives for cooperation might need to be mobilized to improve the prospects of success in these complex areas of policy conflict.

Conclusions

The evidence-based policy movement in recent decades has been successful in expanding the scope of evidence and analysis available for decision makers, and demonstrating the advantages of a more rigorous approach to understanding trends, causality, and the effects of particular interventions. Tools for analyzing policy options and evaluating program outcomes are much more sophisticated, and more widely deployed, than some decades ago. The democratic dissemination of information and commentary, the wide accessibility of evaluation studies, and a proliferation of research-literate organizations, have all led to a more open policy-making system in many countries. In principle, this has entailed evidence-informed policy contestation and higher levels of public accountability for decision makers. In other countries that lack a democratic and pluralist political culture, the accountability benefits of evidence-based policy processes are sidelined, with the ruling elites selecting which technocratic initiatives will be developed.

In general, the large volume of policy-relevant research and evaluation has had a positive impact. Improvements in the scope and depth of research, and in the links with the policy process, are widely seen as worthwhile. However, establishing close linkages between scientific research and policy making will be a long struggle at many levels. The dream of achieving large and rapid improvements in policy and practice through closer integration with rigorous research has moderated somewhat. Advocates of closer links between rigorous evidence and policy making have pragmatically recognized the inevitability of working with a range of methodologies and forms of knowledge. Rigorous research findings are not available in many significant and emerging problem areas, so that policy decision making under conditions of uncertainty will remain the norm. The inherent institutional and cultural barriers between research, policy, and practice are considerable and long standing. Policy managers and political leaders are motivated and influenced by many factors besides research evidence. For these and other reasons, inserting research evidence into the center of policy decision making remains difficult.

Several features of democratic policy systems pose ongoing systemic obstacles to evidence-based policy making. First, the politicized context of government commitments and decision making creates dispositions in favor of certain policy ideas, regardless of objective evidence. This will remain a feature of political decision making. Second, evidence is always contestable and is often used in partisan ways. Hence, disputes about the interpretation and selection of evidence will continue. Third, public officials do not necessarily have up-to-date awareness of salient research, and much of their research-related effort may be directed at short-term problem fixing rather than at longer term analysis. Finally, the independent research community is often disconnected from the needs and expectations of public officials, with the consequence that research findings are not well targeted and not well communicated.

Thus, in the turbulent context of policy decision making, policy systems may well continue to become more evidence informed, but leaders remain unable to manage politically the large-scale problems of a globalized world, such as the policy

crises around economic stabilization, environmental stewardship, poverty, migration, and civil war. Rigorous scientific methods could serve to increase the credibility of social science approaches to major problems, but the policy system cannot become fully evidence-driven. Unrealistic expectations that better science will inevitably drive better policies have recently been scaled back, as reflected in the phrase 'evidence-informed' policy.

Policy Cycle

Michael Howlett and Sarah Giest, Simon Fraser University, Burnaby, BC, Canada

Abstract

Analyzing policy development in terms of policy cycles and policy styles is useful for several reasons. Not only does it help to make sense out of the different models put forward earlier in the history of policy studies, such as the rational, incremental, and garbage can models of public policy decision making, it also helps to advance studies of these models by specifying the conditions under which different styles of policy making occur. This article sets out the logic of the policy cycle model and justifies its five-stage vision of that process.

The Policy Cycle Model of the Policy Process

The idea that the policy process can be thought of as a series of steps in a cyclical model of decision making was first broached systematically in the work of Harold Lasswell, a seminal figure in the development of the policy sciences at the University of Chicago and Yale University in the early 1950s (Lasswell, 1956, 1971). At present, a five-stage model of the policy process is the most commonly used, although many other versions exist with more fewer substages. In this model, 'agenda setting' refers to the first stage in the process when a problem is initially sensed by policy actors and a variety of solutions put forward (*see* Agenda Setting, Public Policy in). 'Policy formulation' refers to the development of specific policy options within government when the range of possible choices is narrowed by excluding infeasible ones and efforts are made by various actors to have their favored solution ranked highly among the remaining few. 'Decision making' refers to the third stage in which formal actors in government adopt a particular course of action. In the fourth stage of 'policy implementation,' governments put their decisions into effect using some combination of the tools of public administration in order to alter the distribution of goods and services in society in a way that is broadly compatible with the sentiments and values of affected parties. Finally, 'policy evaluation' refers to the fifth stage in the processes in which the results of policies are monitored by both state and societal actors, often leading to the reconceptualization of policy problems and solutions in the light of experiences encountered with the policy in question and the start of a new iteration of the cycle (Howlett et al., 2009).

This idea of policy making existing as a set of interrelated stages provides a general 'framework' for understanding the policy development process and points to several of the crucial temporal activities and relationships that should be examined in furthering the study of the issue. Although a useful conceptual or analytical tool, the policy cycle model has some limitations as an empirical description of policy-making reality due to its simplification of highly contingent and complex policy processes. The reality of policy making is not as systematic and linear as the model might suggest. Also, the stages are often compressed, skipped, or change their order entirely. For example, policy formulation can sometimes precede agenda setting, as 'solutions seek problems' to which they can be applied (Kingdon, 1984; Howlett et al., 2009). It also does not answer several key questions such as the actual substance of policy, the number and type of relevant actors involved in the process, the exact manner and sequence in which actual policy development processes occur, and whether there exist basic patterns of development in different issue areas, sectors, or jurisdictions (Sabatier, 1991).

Overall, when using the policy cycle idea, diligent attention has to be paid to the fact that the model is a guideline for the analysis of a far more complex reality.

Styles of Policy Behavior in the Policy Cycle

Empirical studies of policy-making processes undertaken to answer these questions and generate more precise models of the policy-making process have developed more specific knowledge about the interactions of policy actors at each stage of the cycle, summarized below. These draw attention to the limited number of common modes, or *styles*, which characterize policy processes throughout the world. A policy style is also often part of a larger 'policy regime' that emerges over time and includes not only how policy deliberations take place, but also the kinds of actors and ideas present. As such, it is useful in identifying long-term patterns in content and process of public policy making (Howlett et al., 2009). Common policy styles at each stage of the policy cycle characterize the principal components of policy dynamics. A policy style describes how governments go forward during, for example, the agenda-setting stage and which effects result from that stage for the ongoing policy-making process. They are tools for understanding the problem-solving directions of actors in the cycle and for revealing the institutional routines and procedures underlying policy processes.

Agenda Setting

In the scholarly literature on agenda setting, a useful distinction is drawn between the *systemic* or unofficial public agenda and the *institutional* or formal, official, agenda. The systemic agenda "consists of all issues that are commonly perceived by members of the political community as meriting public attention and as involving matters within the legitimate jurisdiction of existing governmental authority" (Cobb and Elder,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.75031-8

1972, p. 85). This is essentially a society's agenda for the discussion of public problems, such as crime or health care, water quality or wilderness preservation. The formal or institutional agenda, on the other hand, consists of only a limited number of issues or problems to which attention is devoted by policy elites (Baumgartner and Jones, 1991; Kingdon, 1984).

Research conducted by John Kingdon into the dynamics of agenda setting in the US Congress in the early 1980s focused on the timing of agenda entrance. In his work, he focused on the role played by policy entrepreneurs both inside and outside governments in taking advantage of agenda-setting opportunities – policy windows – to move items onto formal government agendas (Kingdon, 1984). Kingdon argued that the characteristics of issues (the problem stream) combined with the characteristics of political institutions and circumstances (the politics stream) and the development of policy solutions (the policy stream) lead to the opening and closing of opportunities for agenda entrance. Such opportunities can be seized upon or not, as the case may be, by policy entrepreneurs who are able to recognize and act upon them. The policy windows resulting from this include routine, spillover, discretionary, and random types (Kingdon, 1984). Empirical evidence suggests that the frequency of occurrence of the window types varies by level of institutionalization – with the most institutionalized types occurring much more frequently than the least institutionalized. This lends the model a degree of predictability in terms of the occurrence and type of policy window.

Almost 40 years ago, the American political scientists Cobb, Ross, and Ross developed a model of typical agenda-setting styles. In their analysis, they argued that three basic patterns of agenda setting could be discerned, distinguished by the origins of a policy issue as well as the resources utilized to facilitate its inclusion on the policy agenda. In the outside initiation pattern, "issues arise in nongovernmental groups and are then expanded sufficiently to reach, first, the public [systemic] agenda and, finally, the formal [institutional] agenda" (Cobb et al., 1976). The *mobilization* case is quite different and describes 'decision-makers trying to expand an issue from a formal to a public agenda.' In this model, issues are simply placed on the formal agenda by the government with no necessary preliminary expansion from a publicly recognized grievance. In the third type of agenda setting, inside initiation, influential groups with special access to decision makers initiate a policy and do not necessarily want it to be expanded and contested in public.

Policy Formulation

Studies of policy formulation have emphasized the importance of actors interacting to develop and refine policy options for government (Freeman, 1955; Linder and Peters, 1990). But unlike agenda setting, where many members of the public may be actively involved, in policy formulation the relevant policy actors are typically restricted to those who not only have an opinion on a subject, but also have some minimal level of knowledge that allows them to comment, at least hypothetically, on the nature and feasibility of options put forward to resolve a policy problem.

The power of ideas and their stability in policy subsystems, in particular, has been a subject of much attention in studies of policy formulation in recent years. Carstensen (2011), for example, has suggested that ideas change incrementally, when new elements of meaning are added to them, resulting in a characteristic process of policy formulation in which similar ideas inform similar policy options developed over long periods of time. Focusing on the information or knowledge available to decision makers has led policy research in this vein to focus on the role of epistemic or policy communities in policy formulation (see Haas, 2012). These are loose groupings of experts who serve as knowledge 'providers' for the decision-making process – opening up opportunities for them to influence the content and timing of policies (Dunlop, 2009, p. 290; Haas, 1992).

Scholars over the years have developed a variety of taxonomies to help identify who the key actors in these policy subsystems are, what brings them together, how they interact, and what effect their interaction has on policy development. Most of these distinguish between a larger set of actors with some knowledge of the policy issue in question, and a smaller set in which actors not only have requisite knowledge, but also have established patterns of more or less routine interactions with each other (Knoke, 1993).

Membership in knowledge-based policy *communities* extends to actors such as state policy makers (administrative, political, and judicial), members of nongovernmental organizations concerned with the subject, members of the media who report on the subject, academics who follow or research the area, and members of the general public who, for whatever reason, have taken an interest in the subject (see Thatcher, 2012, Issue Networks: Iron Triangles, Subgovernments, Policy Communities, Policy Networks, Sabatier, 1987). In many issue areas, the policy community also involves members of other organizations such as businesses, labor unions, or various formalized interest groups and even international actors such as multinational corporations (Haas, 1992). A subset of these actors who interact within more formalized institutions and procedures of government are defined as members of *policy networks* (see Coleman, 2012, Policy Networks). These policy networks include representatives from the community, but are 'inner circles' of actors, who effectively hold the power to veto or disparage many policy options as untenable or infeasible.

In this view, the likely results of policy formulation are contingent upon the nature and configuration of the policy community and network in the specific sector concerned. A key variable that many observers have argued affects the structure and behavior of policy networks is their number of members, which affects aspects of networks such as their level of integration and the types of interactions members undertake with each other (van Waarden, 1992). What is important for policy communities, on the other hand, is not the number of participants in the community so much as the number of relatively distinct 'idea sets' that exist within it. This affects the nature of conflict and consensus that exist in the community and, as a result, impacts the behavior of community actors.

In open subsystems where networks have many members and communities share many idea sets, it can be expected

that a propensity for new, radical alternatives to the status quo may be generated in the policy formulation process. In closed subsystems, where networks have few members and communities are dominated by a single idea set, on the other hand, a status quo orientation is likely to emerge in the policy options developed and put before decision makers.

Although the networking framework has been criticized as being primarily a descriptive metaphor, due to the fact that "the independent variables, (of policy-making) are not network characteristics per se but rather characteristics of components within the networks" (Dowding, 1995, p. 137), it provides a general mechanism to organize the complex reality of multiple actors, institutions, and ideas found in policy formulation and generates a relatively parsimonious model of formulation styles (Howlett et al., 2009).

Decision Making

Many early studies of policy making in companies, governments, and organizations, conducted largely by the students of public and business administrations, argued decision makers attempt to follow a systematic method for arriving at logical, efficient decisions. They argued that policy makers achieved superior results when they first established a goal, explored alternative strategies for achieving it, attempted to predict its consequences and the likelihood of each occurring, and then chose the option that maximized potential benefits at least cost or risk (Cahill and Overman, 1990).

This model was 'rational' in the sense that it prescribed a standard set of procedures for policy making, which were expected to lead in all circumstances to the choice of the most efficient means of achieving policy goals. Such pure 'rational' models of decision making often thought of policy makers as neutral 'technicians' or 'managers,' who after identifying a problem would find the most effective or efficient way of solving it. Many of the latest efforts to enhance the efficiency and effectiveness of public policy decision making, such as the 'evidence-based policy movement' (*see* Policy Analysis: Evidence-Based Policy Making), focus on the application of a systemic evaluative rationality to policy problems in classic rational style.

Empirical research into decision-making processes, however, has discovered that political processes of bargaining and negotiation often outweigh 'rational' deliberations and calculations of costs and benefits in public policy decision making. Policy makers were often found to be neither necessarily neutral nor competent and other models of the public policy decision-making processes have argued this is not an accidental situation but rather an inherent and unavoidable characteristic of the policy-making exercise. Therefore, critics of the rational model, such as Herbert Simon, noted that there are definite cognitive limits to the decision makers' ability – 'bounded rationality' – to consider all possible options, which forces them to selectively consider alternatives. 'Satisficing' behavior, in which decision makers did not consider all options in an effort to maximize policy impact but rather simply agreed on a path that they found 'satisfactory,' was argued to better reflect the reality of decision making in a public policy context (Simon, 1955; Smith and May, 1980).

The well-known incremental model of policy making developed by Yale University political scientist Charles Lindblom incorporated these insights into the best known alternative to the classic rational model (Dahl and Lindblom, 1953; Lindblom, 1959). Lindblom summarized the elements of his model as consisting of 'mutually supporting set of simplifying and focusing stratagems.' These resulted, as he put it in his oft-cited 1959 article on "The Science of 'Muddling Through,' in decision makers working through a process of 'continually building out from the current situation, step-by-step and by small degrees' or 'increments'" in which policies were invariably developed through a process of 'successive limited comparisons' with earlier ones with which decision makers were already familiar (Lindblom, 1959).

Taking these insights into account, Braybrooke and Lindblom (1963) argued that different styles of decision making could be discerned depending upon the amount of knowledge at the disposal of decision makers, and the amount of change the decision involved from earlier decisions. Other authors, like Graham Allison, also developed similar models of distinct decision-making styles (Allison, 1971), but did not specify in any detail the variables that led to the adoption of a particular style.

Attempting to improve upon these models, John Forester (1984) suggested that decision making was affected by the number of agents involved in a decision, their organizational setting, how well a problem is defined, the information available on the problem, its causes and consequences, and the amount of time available to decision makers to consider possible contingencies and their present and anticipated consequences. In this model, decision makers situated in complex subsystems are expected to undertake adjustment strategies while those dealing with simple configurations of actors and ideas will be more prone to undertake search-type 'rational' strategies. The nature of the decision criteria, on the other hand, varies with the severity of the informational, time and other resource constraints under which decision makers operate. Hence, decision makers faced with high constraints will tend to favor satisficing over optimization, itself an outcome more likely to occur in situations of low constraint.

Policy Implementation Styles

Generally speaking, comparative studies have shown that governments tend to develop specific implementation styles as they go about the course of their business (Knill, 1998; Hawkins and Thomas, 1989; Kagan, 1991). These styles combine various kinds of policy instruments – such as public enterprises, regulation, or public consultation – into a more or less coherent whole, which is consistently applied in specific sectors of government activity – such as health policy or industrial policy. These policy tools provide the substance or content needed to implement what was planned in the formulation stage and decided upon afterward (Salamon, 1989).

These tools fall into two types. *Substantive instruments* such as regulation or public enterprises are those directly providing goods and services to members of the public or governments. They include a variety of tools or instruments relying on different types of governing resources – such as money, information, authority, or organizational resources (Hood,

1986) – for their effectiveness. *Procedural instruments*, on the other hand, such as public hearings or commissions of inquiry, are different from substantive ones in that their impact on policy outcomes is less direct. Rather than affect the delivery of goods and services, their principal intent is to modify or alter the nature of policy processes themselves.

Studies such as the work of Gunningham et al.'s (1998) 'smart regulation' led to the development of efforts to identify complementarities and conflicts within instrument mixes or tool 'portfolios' involved in more complex and sophisticated policy designs. Each tool mix decision combines advantages and disadvantages of each tool in its relationship to other tools as well as the effect it has on costs and benefits for government.

Why a particular combination of procedural and substantive instruments is utilized in particular policy issue areas is a key question affecting implementation and implementation studies. The preferences of state decision makers and the nature of the constraints within which they operate are among the factors affecting policy implementation and instrument choices that lead to the development of specific preferences or styles (Freeman, 1985). A state must have a high level of administrative capacity, for example, in order to utilize authority, treasure, and organization-based instruments in situations in which they wish to affect significant numbers of policy targets. When it has few of these resources, it will tend to utilize instruments like incentives or propaganda or rely on existing voluntary, community, or family-based instruments (Howlett et al., 2009). Similarly, a key feature of procedural instrument choice is a government's capacity to manipulate policy subsystems (Mayntz, 1975).

Policy Evaluation Styles

The last stage of the policy cycle is policy evaluation. For many early observers, policy evaluation was expected to consist of assessing if a public policy was achieving its stated objectives and, if not, what could be done to eliminate impediments to their attainment. Thus David Nachmias (1979) defined policy evaluation as "the objective, systematic, empirical examination of the effects ongoing policies and public programs have on their targets in terms of the goals they are meant to achieve." However, while analysts often resorted to concepts such as 'success' or 'failure' to conclude their evaluation, Ingram and Mann (1980) caution that such concepts are slippery and often highly subjective. That is, public policy goals are often not stated clearly enough to find out if and to what extent they are being achieved, nor are they shared by all key policy actors.

What is significant in the evaluative process is thus not so much ultimate success and failure, but that policy actors and the organizations and institutions they represent can *learn* from the formal and informal evaluation of policies in which they are engaged. This can lead them to modify their positions in the direction of greater substantive or procedural policy change, or it can lead them to resist any alteration to the status quo.

Policy evaluations do not necessarily result in major policy change. That is, while the concept of evaluation suggests an implicit 'feedback loop' is an inherent part of the policy cycle, in many cases this loop may not be operationalized or may result in only incremental changes to the status quo (Pierson, 1993). Path dependence, in which policies are set on 'trajectory' following some 'critical juncture' can hinder policy change and learning (Pierson, 2000). Organizational–institutional designs which limit 'absorptive capacity' are also often seen as barriers to learning from policy evaluations.

A significant variable in this regard is the capacity of an organization to absorb new information (Cohen and Levinthal, 1990). Only when state absorptive capacity is high would one expect any kind of learning to occur. If a relatively closed network dominates a policy subsystem, then learning is likely to be restricted to some form of 'lesson drawing,' in which policy makers draw lessons from past uses of specific policy instruments (Rose, 1991). Open subsystems allow for 'social learning' when administrative capacity is high and more informal evaluation takes place among all those affected by a policy (Howlett et al., 2009; Bennett and Howlett, 1992).

Conclusion: Policy Development as Policy Style

As Lasswell noted in the 1950s, envisioning policy development as a staged, sequential, and iterative process is a useful analytical and methodological device. Methodologically, such an approach reduces the complexity of public policy making by breaking down that complexity into a small number of stages and substages, each of which can be investigated alone or in terms of its relationship to any or all the other stages of the cycle. The policy cycle idea also helps to answer many key questions about public policy making regarding the effectiveness of different tools and the identification of bottlenecks in policy processes. The stages model allows for the identification of specific actors and actions in different phases of tackling a problem, which makes it easier to measure the impact of key variables on policy outcomes and to identify existing policy process styles.

Abstract

This article assesses the nature of foundations and their role in policy and for civil society more generally. It covers the historical roots of foundations and also reflects on new developments in the field. Additionally it contemplates on the foundation's role in international development cooperation as well as within the American university system. Lastly the article discusses debates and criticisms generated around the topic and draws a comparison between the history of foundations in the United States and in Europe.

Foundations have been among the oldest social institutions, prevailing for thousands of years. Their existence in various forms and across many cultures throughout history has remarkably expanded in the immediate past few decades of flourishing international and national institutional philanthropy (Johnson, 2010). By the turn of the century, there were more foundations with more assets in more nations than ever before. Although endowment values dropped in 2001 and 2008 in most developed market economies, they still remain at historically high levels.

In enabling donors to reserve and invest charitable funds, setting terms for their contribution, providing funds to one or many grantees over time, and relocating funds from one charitable activity to another, foundations play an important role. In their civic capacity (comparable to associations and nonprofit organizations), they represent sources of wealth, influence, and initiative, independent of government and business. Foundations can help individuals discharge religious obligations and moral commitments; provide a secure base for religious, cultural, and scientific interests of minorities; and enable ambitious people to exchange economic wealth for social recognition and prestige (Anheier and Hammack, 2010).

Roots of Foundations

There is a lot of discussion about the origins of foundations, which depend on the definition of the term and its geographical focus. Smith and Borgman (2001) identify two prominent roots in the development of foundations in Europe; first religion, namely the Roman Catholic and the Protestant churches, and secondly the 'bourgeois' revolution of the nineteenth century, when the foundation's format was frequently used by the emerging urban middle class and the industrial elite. Early in history, philanthropy was regarded as a charitable attitude which was mainly exercised by religious groups or by royal families, as these institutions were influential in shaping society and making policies. In the introduction to *American Foundations: Roles and Contributions*, Anheier and Hammack (2010) point out how medieval and European philanthropies supported the saying of prayers, the education of religious leaders, the symbolic feeding of the poor, and the religious care of the sick and dying. Later in the eighteenth century, enlightened persons like Webster, Jefferson, and Smith thought of individual charitable giving and assistance as being in the general interest of civil society. In 'The Theory of Moral Sentiments,' Smith referred to benevolence as an universal part of what makes us human (Friedman, 2002: p. 7). Although charity still exists as a fundamental attitude, since the late twentieth century charitable activities have taken a more institutional form for long-term problem solving relating to the new social order. Furthermore, in the course of the twentieth century, scholars from all over the world have come to study nonstate actors and the nonprofit sector. Starting from the beginning of the twenty-first century, a very large body of scholars has focused on the nature and processes of philanthropic activity in the American and European nonprofit sector. Although there are still some limitations with regard to scientific findings, foundations and their role in civil society have become topics for research within the social sciences.

Roles of Foundations and Their Impact on Policy Making

Starting from the mid nineteenth century, foundations have adopted broad and ambitious goals. Health and education (e.g., funding for research, libraries, and educational programs) have been particularly well funded by foundations. Dennis Beatrice (1993) calls foundation's role "one of product development for government on politically charged issues" and Anheier and Hammack (2010) summarize the role of foundations in *American Foundations: Roles and Contributions* as follows:

> Philanthropy describes foundations efforts to create something new in one of the three ways: innovation in social perceptions, values, relationships and ways of doing things, which has long been a role ascribed to foundations, although any effort to innovate can fail and can yield negative as well as positive results, original achievements in the arts, in science and in the study of society and social and policy change whereby foundations foster recognition of new needs, seek to bring a wide range of perspectives to the take, encourage discussion of structural change in the interests of such general social goals as efficiency, equity, peace, social and moral virtues of all kinds, law and order or economic growth.
>
> p. 10

From acting as charitable facilitators and social contributors for a better society, foundations have become major players in policy making. Although they do not have the power to get strong public support, foundations, on the other hand, influence public policy by sharing knowledge. Through their activities, they help to bring issues to public attention and support the assessment of proposed solutions to problems. In many countries, foundations act to take care of problems years before governments notice them (Weissert and Knott, 1995). Although the role of foundations in policy making has been largely ignored within public policy literature, by funding researchers to perform high-quality research in policy areas, they contribute to a great extent to public policy discourses, without taking a specific stance.

Debates around Foundations

Despite the fact that foundations have been successful over many years, they also tend to be subjected to severe criticism. There are various interlinked levels of criticism of the foundation's role in and for society, its internal procedures, as well as around the 'philanthropic' concept as such.

It is argued that foundations stand for the inappropriate use of private funds to influence the public policy sphere and therefore interfere with the democratic process. Furthermore foundations are said to determine and pursue their own priorities with a mix of private and public (in terms of forgone tax through exemptions) funds, without control by the elected government. As institutions without shareholders, voters, or customers, foundations can perhaps be described as the most 'unaccountable' organizations in democratic societies (Anheier and Leat, 2013). Additionally they have been accused of acting in a neocolonialist manner – i.e., wealthier countries aim to dominate poorer states. Contributors to *Charity, Philanthropy and Civility in American History* (Friedman and McGarvie, 2002) point out how during Second World War and the Cold War, philanthropic movements became powerful instruments for governments to advance their visions and targets.

Regarding internal processes, foundations are criticized for the lack of accountability and for the inefficiency of their programs. They are accused of failing to recognize their own limitations and they are blamed for favoritism and paternalism (Anheier and Hammack, 2010).

However it is not only foundations that have been criticized; the intentions of major philanthropists have also been questioned over time. Slavoj Žižek (2006) argues:

> This is what makes a figure like [philanthropist] Soros ethically so problematic. His daily routine is a lie embodied: Half of his working time is devoted to financial speculations and the other half to humanitarian activities… that ultimately fight the effects of his own speculations. Likewise the two faces of Bill Gates: a cruel businessman, destroying or buying out competitors, aiming at virtual monopoly, employing all the dirty tricks to achieve his goals … and the greatest philanthropist in the history of mankind.
> pp. 42–43

Argandoña (1990) further contends in his paper about the ethical arguments of donorship and charity, that donorship always represents a kind of greed, pride, and superiority; this implies that the act of donating increases the ego of the giver and places him on a superior level in relation to the receiver (p. 6).

Nonetheless, one cannot deny that foundations have greatly contributed to social changes, particularly in the fields of education and health. Nowadays, foundations are everywhere in demand, for example, an artist looking for a patron, a local soccer team in financial difficulties, a community school planning to build new facilities or to buy computers, unemployed workers applying for financial help, all look for sponsorships from foundations. Eikenberry and Nickel (2006) argues that philanthropy is dependent upon the existence of marginal groups in need of assistance and a more powerful group in a position to offer this assistance.

While foundations have been publicly criticized, empirical studies have demonstrated that policymakers have pretty much a positive opinion about the work of these institutions. Using an empirical method, Weissert and Knott (1995) conducted a pilot study with a representative sample of policymakers in the United States. Respondents were asked to compare foundations with think tanks and interest groups in respect of their desire to serve the public interest, their compliance with nonpartisanship, and their advocacy for unpopular ideas. In contrast to the recent perception among politicians and academics, which perceived foundations as partisan, nearly three-fourths of the interviewed believed that foundations were nonpartisan compared with the other groups, and additionally, 80% said that foundations were more likely to spend money on novel ideas. Respondents were also asked to evaluate funding approaches and 78% of them accounted funding for protests as extremely useful or very useful for policy making; another 58% indicated the development of informative reports or commissions as especially useful instruments (Weissert and Knott, 1995).

In his book *American Philanthropy*, Robert H. Bremner (1988) argues in favor of philanthropists and claims that whatever the motives that animate the individual philanthropist, the purpose of philanthropy itself is to promote the welfare, happiness, and culture of mankind. Bankers Trust (2000) conducted a study of 112 wealthy households to examine the notion of 'wealth with responsibility.' The idea was to get a measure on how much the wealthy were giving back to society in terms of charitable giving; 90% of respondents stated that they have established an asset plan, which leaves 16% of their assets to charities, 47% to their heirs, and 37% to government in the form of taxation (Boettke and Coyne, 2002). However, the measurement of effectiveness of this charitable giving remains an ongoing debate.

Emergence of a New 'Philanthropy'

All the debates on the purposes, the ethics, and the effectiveness of foundations have also brought up new ideas on how to improve accountability, efficiency, and the managing strategies of these institutions. Therefore the past decade has witnessed the emergence of a new 'philanthropy' characterized by large-scale investment and more result-based mechanisms.

Critiques on traditional philanthropy range from accusing them of faults ranging from being too powerful and immune to public opinion, to being too accessible to organizations seeking to realize social change. Starting from the beginning of the twenty-first century, foundations and philanthropists believed that they could greatly improve the efficiency of their programs by using the same strategies and principles that contributed to their financial success. Since then, foundations have come to change the ways in which they operate and new 'venture philanthropic foundations' have emerged, mainly characterized by long-term and large-scale engagement and strategic similarities to venture capitalists. The term 'venture philanthropy' (VP) was probably first coined in 1969 by the American philanthropist, John D. Rockefeller III, in a hearing before the US Congressional Committee leading to the Tax Reform Act (John, 2006). Scholars are intrigued by this new trend in philanthropic activity and have been researching the major differences between traditional foundations and the new ones.

In her research on VP and charter school reform, Janelle Scott (2009) outlines some basic differences between the traditional form of foundations and VP foundations. She points out that contrary to traditional foundations (which carry out a specific ideology or social policies and share the funding costs between the same grantees), the new VP foundations provide unrestricted general operating support on a multi-year basis at much higher rates than traditional philanthropies. The two groups of foundations also differ in their philosophical approaches to funding. While traditional foundations typically identify broad program areas and invite applications for funding, VP foundations often choose to fund promising leaders and organizations instead. For instance, many of the new VP foundations do not accept grant proposals, for example the Robertson Foundation. It is a family foundation founded in 1996 which identifies the programs that are relevant to its tenets. Therefore its website describes the relating funding philosophy as follows: "The Robertson foundation takes a targeted, businesslike, results-oriented approach that is modeled more closely on private equity investing than on traditional grant making." In her publication, Scott also stated that the most relevant innovation is the utilization of terminologies: for VP foundations: grants have become investments, programs are ventures, and measures of impact generally involve the ability to scale up an initiative (p. 115).

While some scholars praise the new VP foundations in achieving greater results, others criticize and doubt that there is real innovation in their operations. Covington (1997) argues that although a new cadre of foundations has emerged pursuing more aggressive funding programs than traditional foundations, these funding initiatives have been largely already adopted by politically conservative foundations, which have been applying such strategies for some time. Cohen (2007) also doubts that the 'new' philanthropy is truly new. His examination of the new VP foundations revealed striking similarities between the strategies used by these newer philanthropies and those of politically and socially conservative foundations. Therefore, VP foundations seem to have much in common with the traditional foundations in terms of strategy and philosophy.

Though there is not a large amount of published literature on the new VP foundations, there is ongoing criticism about their actions. According to research by Ramdas (2011) VP practices seem to be motivated by technological solutions – the same 'fix-the-problem' mentality that allowed business people to succeed as hedge-fund managers, capital-market investors, or software-developers. This approach is designed to yield measurable and fairly quick solutions but may not always be effective in the world of philanthropy. Therefore, she points out that despite many good intentions, this version of philanthropy seems poorly suited to resolve the world's most pressing and deeply rooted problems.

Foundations and the American University System

As the United States has by far the world's largest foundation sector and offers something close to a 'gold standard' for other countries, it is important to highlight the role of foundations in the United States and especially its place in the American university system (Anheier, 2009; Anheier and Leat, 2013).

In the beginning of the twentieth century the universities in the United States were geographically widespread and mostly private institutions. They were mainly financed by the tuition fees of students and the quality of education was often of a low standard. Local foundations supported colleges with religious affiliation, mostly to strengthen Protestant education – and this gave the colleges a certain independence. However with the emergence of new foundations, among them Carnegie, Rockefeller, and Rosenwald, a new orientation of foundation work started. They strongly supported a system of academic research and professional teaching on a world class level with strategic interventions. Criticism evolved concerning the influence of these 'nouveau riche' philathropists, arguing that they try to control public welfare rather than serve society with an altruistic orientation. As a response to this criticism, foundations started focusing more on national needs.

Furthermore these new foundations started to create innovative systems, not only to support research projects, but also to establish a support system for academics in general as well as the development of selected individual disciplines. Since at the beginning of the twentieth century there were only a few world-class American scholars, the Rockefeller Foundation started to establish centers of excellence to make the United States competitive in international competition. The approach of these foundations consisted in supporting ultramodern laboratories, putting together clusters of excellent graduates, and bringing in highly qualified researchers from Europe to the United States. They also started to build up interuniversity institutions. For instance the Carnegie Institute and the Rockefeller Foundation built the most modern telescopes in years 1908 and 1917 in Texas. With investments of this kind, foundations generated essential support for interdisciplinary institutions. They also provided assets for the American Council of Learned Societies and the Social Science Research Council, through which they helped to build up the National Center for Economic Research. Furthermore they improved the overall economic situation of professors and academic employees.

The priority of most of the foundations was given to natural science rather than to humanities or cultural studies. But

already in these days, Rockefeller, Carnegie, Russell Sage, and others began to think about investment in the emerging field of social sciences. There were several approaches in this regard; for example, the Carnegie Corporation invested strongly in the study 'An American Dilemma,' one of the most important studies about the situation of minorities within the United States. However the problem with social science was its inherent evoking of political controversies. They dealt with topics, which lay at the core of religious and political conflicts. This was the reason why foundations acted in a very cautious manner and placed strong emphasis on accurate elaborated empirical studies. Social studies then had their breakthrough during the Second World War. With the financial support of the state they started engaging in strategic research on the morale of the troops and similar topics. This and other future-leading project funding could be based on (also established with the help of the foundations) the already created fundaments within the social sciences.

As the US system is a mixture of private and public institutions, the state is only expected to be partly held responsible for funding the universities. Since the 80s the Federal Government began shifting 'from grants to loans' and kept the funding of university-based research below the inflation rate. One can also observe a shift from state-funded to state-supported universities. Universities became more dependent on tuition fees, as well as on money from companies and foundations. The financial structure of private and public institutions was assimilated and the competition between the institutions increased. After Second World War, although the Federal Government still played a very important role in terms of funding universities, the strong relationship between foundations and universities still persisted, but evolved in new ways.

Nowadays foundations are hardly responsible for the core budgets of universities, but they invest in specific programs and projects as well as in the establishment and development of institutions. Next to the pattern of competition as the basic policy of foundations in respect of higher education, there are also longlasting cooperations and partnerships. Big parts of the Danforth Foundation, for example, are funding the Washington University of St. Louis, and recent foundations like the Hewlett Packard foundation are funding, to a large extent, the University of Stanford and the University of California. Within these cooperations there are recognizable disciplinary patterns, for example, the Mellon Foundation focuses on humanities, the Welch foundation on chemistry and the Wenner-Gren Foundation on anthropology. Although the donations of foundations for the university system represent a quarter of their assets, for the universities it is only a small part of their total income (below 5%). They receive the biggest parts through tuition fees and public funding, as well as through their property and state donations. These gains considerably increased in comparison to the funding from foundations for universities. Foundations still support innovation in the academic system and provide substantial resources, but they are not any longer able to influence universities to the extent they did at the beginning of the twentieth century. Nowadays they place more emphasis on certain restricted areas with special purposes and increasingly cooperate with other supporters and financiers (Anheier, 2009).

Foundations and International Development

Another topic that has attracted considerable attention from scholars is the involvement of foundations in international development efforts. The first interventions by foundations in the area of international development date back to the 1920s, with groundbreaking action in the public health sector undertaken by the Rockefeller Foundation (Sulla, 2007). Later on, with globalization and the increase in international social contributions for developing countries, foundations have evolved as new actors in the area of funding for international development.

In many developing countries or failed states, the incapacity of the government to meet the needs of the population has led to a growing preference for nongovernmental action as a means to solve societal problems. Foundations have therefore expanded their coverage from a regional level to an international level. As wealthy philanthropists invest billions of dollars on development efforts in Sub-Saharan, Asian, and Latin-American countries, their role in the international development agenda has evoked significant public attention. This kind of development assistance also stands for a world characterized by increasing interconnections beyond national boundaries and problems with global implications. Foundations have been playing an especially important role in fighting worldwide diseases, such as AIDS, Tuberculosis and Malaria. International foundations have also been engaged with the promotion of democratization and support for civil society in areas of limited statehood.

The overall international grants given by foundations from Western countries has doubled over the last decade, and the main recipients of the surplus are developing countries. According to The Foundation Center and Hudson Institute, foundations provided between US$7.0 billion and US $9.5 billion for activity in the sphere of international development. The Bill and Melinda Gates Foundation and Georges Soros' Open Society are concrete examples, both having invested billions of US dollars in Sub-Saharan, Asian, and Latin American countries. There is much speculation on the potential future role of private foundations in the area of development assistance, especially when comparing it with the official development assistance (OAD). Although international development represents only a small share of the overall spending of foundations and although their contribution in contrast to official aid is still small, one cannot deny their potential future impact on international development efforts.

According to Marten and Witte (2008), the Council on Foundations of the United States estimated that there were 68 000 grant-making foundations which gave $3.8 billion for international development in 2005, with the Bill and Melinda Gates Foundation at the top of the list and the Gordon and Betty Moore Foundation in second rank (its assets grew to $5 billion in 2003 and they funded the Andes-Amazon initiative to conserve biodiversity). However, although these numbers might seem to be impressive, only 10% of the grants given by US foundations goes to international development and it is mostly channeled through international institutions like the World Health Organization or through NGOs in Europe, rather than distributed directly to the countries (Sulla, 2007). Research by Sulla (Sulla, 2007) also demonstrates that

the main developing countries directly receiving international assistance from US foundations are the top emerging markets, including Russia, Brazil, India, China, Mexico, and South Africa. The least developed countries seem to be benefiting only slightly from the foundations' direct international flows; and this is mainly due to the difficulty of accessing information on the implementation of the assistance.

In the summer of 2007, the European Foundation Center (EFC), an umbrella organization with more than 200 members, conducted a survey (funded by the German Marshall Fund of the United States) to assess European foundations working in the area of international development. The results highlight the fact that European foundations involved in international development spent around $607 million in 2005; these investments were targeted at 126 countries with only 29 of them belonging to the least developed nations (Marten and Witte, 2008). Nonetheless, in contrast to the USA, Sulla (2007) found that the total international 'grant-giving' of European foundations has been slowly increasing over the last few years, although there is very little information on the sectors of activity to which European foundations have been making international grants.

Philanthropic foundations are said to have many advantages when it comes to international development. It is argued that because foundations can act outside official government channels, they can be more effective than official cooperation, take on more risk, and invest in more innovative projects. They can also reduce transaction costs and respond more quickly to emergencies. They are less subject to misappropriation because they deliver directly to civil society organizations. Additionally, they attract other foundations and potential donors for social development and institutional improvement in areas of limited statehood (Benjamin and Quigley, 2010).

Nonetheless, interventions of foundations in international development have raised criticism. Critics argue that private philanthropy is often supply driven and may not fully align with national development goals and strategies. Benjamin and Quigley (2010) also argue that the downside of foundations as first responders is that they often do not stick around long enough to ensure the long-term sustainability of the institutions that they help to build. Additionally, because their intervention is often off-budget, they might use systems that are parallel to those of governments and thereby complicate governmental financial management; they may also generate high overhead costs for administering small amounts of funds (UN Economic and Social Council Report, 2012).

Other critics fault international foundations with regard to their mode of operation in countries where they invest. Many large foundations working in international development do not have offices in the field and they manage their operations from headquarters in the United States or in Europe; in some other cases, foundations try to stay small although they are faced with the reality of huge budget disbursements that simply require more staff.

Some of the time, the private foundation's work is either led by so-called political philanthropists famous for their business successes or it is supported by celebrities interested in international development. In his book *Fighting Global Poverty: Who'll Be Relevant in 2020?*, Matthew Bishop (2007) argues that this power of personalities coupled with media visibility helps to mobilize and generate public support for development and also fosters interest in developmental issues in the broader public. However, the whole media attention can also exaggerate the work of these philanthropists.

Despite all this criticism, experts in international development tend to support the foundations' work in developing countries. Dr. Watson from the Institute for International Development Studies argues: "Philanthropy can contribute a huge amount to development cooperation. Both private and corporate foundations directed $52.5 billion toward international development in 2009. They can also contribute greatly in many other ways, for example in their convening power, in running pilot programs, in their ability to take risks, and in community engagement, research and advocacy. However, despite the amount of funding, there is slow progress with respect to child nutrition, education, sanitation, urban issues and female employment, and progress is extremely uneven between regions of the world" (http://www.ids.ac.uk/news/philanthropic-foundations-should-be-included-in-discussions-on-development-cooperation (accessed 04.03.14.)).

European and American Foundations: A Comparison

Comparative research on foundations across different countries has only begun in recent years. While research on American foundations started earlier, the study of European foundations is still in its infancy. For instance, research on German philanthropy has only begun in the last 10 years. The impetus for this research stems not from historical interest but from a change in German political culture (Adam, 2001).

While philanthropy has been historically performed by religious communities and royal families in early Europe, researchers have demonstrated that they did not develop a feeling of responsibility and philanthropic impulse. Historians rather have investigated that the state took responsibility for financing social and cultural public institutions. For this reason, philanthropy has been widely seen as an American phenomenon and therefore as a distinct aspect of modern life within the United States.

However in *Philanthropy, Patronage, and Urban Politics; Transatlantic Transfers between Europe and North-America in the Nineteenth and Early Twentieth Centuries*, Thomas Adam (2001) rejected this argument. He states that the travels of American and Canadian philanthropists to Great Britain and Germany in order to find models for museums, art galleries, and social housing projects demonstrate that philanthropy was not an American invention but a European one. Furthermore, by comparing social housing projects in Boston, Leipzig, London, and New York, Adam demonstrated the interconnections among philanthropists from these different countries and showed how American philanthropists implemented European models in US cities.

On the opposite side, Karsten Friedman in the same volume contradicted this view with his investigation of art museums in Germany and the United States after the turn of the century. Focusing on Berlin, he argued that there were fundamental differences between philanthropic support of museums in the United States and in Germany. Whereas American museums were privately owned, German museums were state institutions

that received additional financial support from 'museum associations.'

Toepler (2007) points out in *The Politics of Foundations: A Comparative Analysis* that there are elements that American and European foundations share in common, as well as fundamental differences. Both European and American foundations reject taking over the function of a substituting body, i.e., they are not willing to fulfil functions formerly supplied by the state – for example, redistributing economic resources from higher- to lower-income groups. They both place importance on innovation, which means they engage in promoting innovative enhancements in different fields. Additionally they share a halfhearted acceptance of their pluralistic function as promoters of experiments and diversity in general. However the contextualization of their roles differs. In the United States, the foundation's focus is mainly on social innovation with an undefined relationship to the public sector. The complementary role of serving under-supplied groups is not a big issue in their work. They operate more or less in an institutional vacuum and try to keep their distance from the government and its activities. In contrast European foundations compensate for the institutional shortcomings of the public sector and feel comfortable in their role as complementary actor in the work of the state.

Policy Knowledge: New Liberalism

Abstract

New Liberalism, a contrast term, refers to a movement in social knowledge, public philosophy, state policy, and social practice underway internationally between the 1880s and the 1940s, intended to address the 'social question' raised by instabilities and inequities of modern Western capitalism, and to provide new thinking about relationships between state, economy, and society. New liberals addressed a range of contested issues, among them business cycles and unemployment, rights and conditions of labor, wages and distribution of income and wealth, the limits of property rights, industrial organization and corporate reorganization, family welfare and gender roles, public administration, and issues of immigration and race. Deep divisions over the substance and implications of new empirical and theoretical knowledge on these subjects led to a branching of new liberalism into two distinct new liberal movements elaborated over several decades – a statist-democratic strand of reform thought born in the 1880s, and an opposing, corporate-voluntarist alternative that came together around the turn of the century. The account here identifies five phases in the bifurcated development of new liberalism: (1) market failure and the drive for new social knowledge, (2) conflicting approaches to framing the social question, (3) the 'turn' to social insurance, (4) liberal statism and New Deal planning, and (5) the containment of statist liberalism.

New Liberalism, a contrast term, refers to a movement in social knowledge, public philosophy, state policy, and social practice underway internationally between the 1880s and the 1940s, intended to address the 'social question' raised by instabilities and inequities of modern Western capitalism, and to provide new thinking about relationships between state, economy, society, and the individual. New liberals addressed a range of contested issues, among them business cycles and unemployment, rights and conditions of labor, wages and distribution of income and wealth, industrial organization and corporate reorganization, family welfare and gender roles, immigration and race. Deep divisions over both the substance and implications of new knowledge on these subjects led to a branching of new liberalism into two quite distinct 'new liberal' movements elaborated over several decades. The first to appear was a *statist-democratic* strand of reform thought, born in the 1880s, that proposed more active government in support of economic and social justice. An opposing, *corporate-voluntarist* analysis came together around the turn of the century, aimed at substituting voluntary collective action for much of the state action advocated by those seeking stronger government regulation of work, labor, and business. The term New Liberalism was invented initially by framers in England and the United States to distinguish its early, statist-leaning iteration from, and to set it against, 'old,' classical liberalism, as the latter had developed in the West between the seventeenth and mid-nineteenth centuries around the philosophies of John Locke, Adam Smith, and David Ricardo, and in response to arguments for laissez faire as a default public philosophy. In use internationally between the 1880s and the 1940s, the term referred to a broad-gauged movement intended to address the pernicious instabilities and distributive inequities that modern capitalism had engendered, and to provide new critical thinking about the optimal role of government. From the early twentieth century the terms 'progressive' and 'progressivism' supplanted for some the earlier naming, but both statists and voluntary associationalists could and did claim progressive credentials – a claim that some U.S. historians tend to support. Although the term 'new liberalism' was coined for, and continued to refer to, the move to enhance state power, historians of political ideology and political economy now recognize the binary character of conceptual innovation in this period.

Never a total repudiation of the older classical tradition, new liberalism demanded an exploration of how and where to amend existing commitments to the efficacy of free markets, individual autonomy, secure private property rights, and limited government in light of what had come to be seen as negative consequences of capitalist industrialization. Aiming to frame new methods for shaping and choosing among new civic and social moralities under construction in the industrializing nations of the West, new liberals were ultimately unable to sustain their critical assessment of the classical tradition without changing quite fundamentally their prescriptions for the relationship between society and state.

The account of new liberalism provided here refers mainly to the American case. It identifies five phases in the development of the bifurcated U.S. new liberalism that heightened the visibility of critical moments in its construction. These phases are as follows: (1) a drive for new knowledge prompted by a perception of market failure, (2) formation of conflicting approaches to framing a 'social question,' (3) the 'turn' to social insurance, (4) the rejection of national planning by pro-corporate new liberals, and (5) the containment of liberal statism from the late New Deal through World War II.

Market Failure and the Drive for New Social Knowledge

Chronic business depressions of the late nineteenth century, destabilizing waves of business bankruptcies, mass unemployment, and chronic, desperate poverty alongside ostentatious wealth produced an enormous disappointment of traditional expectations regarding the efficacy of the market.

New liberals recognized recurrent market failure and attendant social conflicts as evidence of a wider collapse, more disruptive to intellectual, social, and political order and more menacing to communities, of a social contract thought ideally to be based on unfettered economic competition between white males that had been exalted in policy discourse during the early nineteenth century. Critics of 'old' liberalism sought a higher rationality that would place knowledge in the service of a more democratically constituted society, which would maintain itself in part by allotting intellectuals and experts a special role in shaping a more vigorous, capable, institutionally developed, morally attuned, and purposeful national government.

Across the range of nations involved, the conceptual revolution that new liberals sought to promote was grounded institutionally in an international social science association movement that fostered transatlantic borrowing, and also in settlement houses, social surveys, and critical journalism, all of them cranked up to record, analyze, and disseminate empirical data, propound theory, encourage the development of political leadership responsive to the new social knowledge and improve the execution of policy. Within government, in investigative agencies such as improved censuses, labor, women's, and children's bureaus, trade boards, regulatory agencies, and bureaus of corporations, high-level civil servants such as Llewellyn Smith and Lord Beveridge in England, and Carroll Wright, Florence Kelley, Julia Lathrop, and Bureau of Corporations chief under Theodore Roosevelt, James R. Garfield, in the United States provided conduits for policy ideas from these burgeoning 'parastates' into government. Crucial early players were founders of the emerging academic social science disciplines, whose missions and boundaries were historically determined, differing from country to country. Academic professionalization and disciplinary specialization proceeded rapidly in the American research universities, fueled by the relative shortage of other types of creditable specialized intelligence.

From the beginning, progressive academics were active in defining what became known in the policy discourse of 1880s as 'the social question.' Strategic rhetorical steps were taken early that shaped the ties between American governance and intellectual life in the period. In the United States, Woodrow Wilson's early and generative 'Science of Administration' (1887) addressed republican fears of corruption by placing a putative firewall between politics and administration. Reflecting distaste for the intense, tribal partisanship of Gilded Age politics, leading academics and bureaucrats (unlike many female social scientists and social reformers, and under some duress) adopted nonpartisanship as a standard description of their professional ethic. This pristine canon elevated everyday standards of disciplinary and agency practice, but pressures for 'objectivity' often hampered the effectiveness of social scientists as advocates for change, ultimately routing important aspects of their activism through ostensibly apolitical venues such as foundations and think-tanks, which often ceded partial control of research agendas to corporate elites. To legitimate their involvement in policy research, academics often sought and accepted roles as 'commissioned' experts, in which they traded a degree of alignment for immunity from outside pressure. The practice of exporting problem solving to private, corporation-sponsored agencies became standard in the Hoover era, a trend reversed in the later New Deal.

Conflicting Approaches to Framing the Social Question

In the struggle to control the direction of change, new liberals of both persuasions deployed rhetorical strategies intended to link their conflicting programs – statist and voluntarist – to carefully selected visions of both the past and the desired future in economic and social policy. Each asserted a connection to the residue of an older individualist doctrine that enshrined private property and competition as the essential guarantees of individual virtue and general welfare, while also explaining how newly experienced social realities had challenged established categories (such as 'the' market) and demanded new forms of collective action. In addition, statist liberals expanded and socialized the republican conception of free labor as the basis of political and economic independence and civic virtue. The elaboration of these two conflicting reform discourses opened up greater possibilities for genuine policy innovation than existed either earlier or since, as in that discrete period, contrary to earlier or later eras, there was nothing close to a hegemonic policy paradigm.

The statist strand proposed translating an aroused social conscience into effective social action through a principled restriction of the meaning of 'private' in many of its applications and through a corresponding expansion of what were to be taken as properly 'public,' morally and socially necessary functions of government. Lamenting the reversal of state-level social regulations in recent court decisions based on newly potent laissez-faire jurisprudence, liberal statists mobilized public agencies in behalf of a reinvigorated *national* interest that they often saw as essential to replace initiatives of individual states and localities traditionally clothed with police powers.

The competing voluntarist vision rejected with equal conviction what, like their predecessor in the old liberal tradition, its founders referred to as 'state interference.' New liberal antistatists preferred to build new ordering strategies upon what they took to be the naturally evolving nongovernmental institutions of a modern society, premier among them the modern business corporation, and upon what they saw as organic, self-activating bodies such as trade associations, professions, charitable organizations, trade unions of strictly limited functions, and peak organizations of private entities, rather than around invigorated legislative democracy, political mobilization, and an empowered, expanding, bureaucratic, regulatory state. They were particularly interested in what could be achieved by way of ordering an excessively competitive and crisis-prone economy through innovative uses of the business contract, working within a powerfully enriched climate of information about the market and – by the turn of the century – through limited banking and tariff reform. Aimed as well at legitimating mergers and restraining coercive job actions by independent labor unions, this effort culminated during the 1920s in the liberal-corporatist design for peak-level business–government cooperation in achieving economic and social stabilization through energized philanthropy and local relief in hard times. Working through proxies, corporate liberals

following Herbert Hoover's lead pressured the worst-acting industrialists to curb voluntarily abuses such as the 12-h day in steel production while offering employee benefits through welfare capitalism.

Liberal statists placed greater confidence in deliberative democracy and less in capitalist rationality or the putative identity of the corporate and the public interest. At the start, drawing energy from heartland republicanism, evangelical Christianity, and German historicism, political economist Henry Carter Adams marked out a path that two subsequent generations of statist-leaning progressives would continue to define as a democratic, moderately collectivist, and communitarian public philosophy. The founding text for the liberal statist view was Adams' classic 1886 article, 'Relation of the State to Industrial Action,' which laid out the costs to society of relying upon the market alone. Adams, along with Richard Ely, Florence Kelley, Edmund James, Simon Patten, John R. Commons, Jane Addams, Mary Van Kleeck, and Charles S. Johnson among numerous others, established a 'context of refutation' for die-hard believers in laissez faire.

For the liberal statists, H.C. Adams pointed to three deficiencies of a regime of market competition that new liberalism would aim to correct: (1) its failure to allow society to enjoy the actual benefits of monopolies in increasing-returns industries without being forced to pay monopoly rents, (2) the inevitable decline of business ethics to the lowest level, absent legal establishment of labor standards, and (3) a general hollowing out of the potential of representative government in a deliberate, misguided weakening of certain key state capacities.

A rising group of new-liberal antistatists led by economists Arthur Hadley and Jeremiah Jenks began forming their own message in the 1890s. Close students of the sources of market failure, these two found great efficiencies in large, capital-intensive industries in transportation and manufacturing; yet they considered even indirect state control of production, wage, and profit levels a threat to the price and investment systems that progressive capitalism could not long endure. With later figures such as Adolph Berle and Hoover aide Edward Eyre Hunt, such thinkers hoped to make the new corporate elites responsible for trans-class and intercorporate cooperation, for providing chances for personal growth and upward mobility along career ladders provided by corporate business, and even for community economic and moral development – to the extent that experience within a corporate culture would inculcate values of efficiency, cooperation, interdependence, and service.

Leading statist liberals can be seen from one perspective as merely seeking to extend the long recognized police powers of the states, used for decades to regulate threats to the public health and safety. Prior to the 1880s, these powers had not been used in newly pressing areas, regulation of labor standards and monopoly. When state legislatures began to move on these issues, state and federal courts initially blocked their actions. As early as 1885 New York State's Court of Appeals, in *In re Jacobs*, struck down a law banning manufacture of cigars in tenement houses, ruling that it violated individual freedom of contract. In the emerging judicial philosophy known as legal formalism, such protective legislation was seen to violate individual due process rights guaranteed by the 14th amendment to the U.S. constitution. In *Ritchie v. People*, 1895, the Illinois Supreme Court applied the same ban against an hours law framed to protect working women. Regarding regulation of monopoly, the decision in *Munn v. Illinois* authorized regulation of rates charged by properties with monopoly positions, such as grain elevators and railroads, whose owners had placed them in the service of the public. But when these constraints on property rights were not extended to regulation of prices and profits in manufacturing monopolies, states turned to an outright ban against monopoly, elevated to the national level in the Sherman Antitrust Act, 1890. This act yielded an unexpected result (also promoted by other factors) when cartel-like combinations involving price fixing agreements between separate businesses were declared illegal, whereas outright mergers that fully absorbed a bunch of smaller manufacturing firms were judged legal. Following the Great Merger Movement, 1898–1902, which gobbled up around 1800 separate businesses, ownership in most core industries was highly concentrated, presenting new policy challenges to both statist liberals and corporate liberals.

As concentration of ownership proceeded in alarming proportions even as economic theorists posited overproduction and competitive price and wage cutting as causes of depressions, labor, populist, and consumer movements challenged new liberals to come up with new ways of addressing the issue. Led politically by Theodore Roosevelt, some liberal statists turned to national level antitrust prosecutions while groping for acceptably bureaucratic means for national regulation. To escape state-level populist pressures, corporate liberals called for transferring regulation of corporations upward, through a system of federal licensing of corporations that established their legality.

From the turn of the century, a dualistic discourse proceeded in which the two opposing strands of new liberalism agreed on departing from laissez faire. Classic texts such as Herbert Croly's *Promise of American Life (1909)* and the Progressive Party Platform of 1912 represented the maturing statist liberal inclination to move aggressively from regulating businesses into national management of natural resources, in which capable, informed governance could instruct a collective interest in conservation, and also into elevating labor standards, extending consumer protection, and establishing a more effective public presence in decisions regarding production, investment, and pricing. Whereas Woodrow Wilson differed on the degree of competition the public interest demanded, he was equally drawn to regulation through state building in areas of clear national-level authority. John Dewey's seminal *The Public and Its Problems* (1927), another powerful exemplar in the new liberal 'role of the state' genre, located the public interest at the place in social relations where effects of contractual relations spilled over onto third parties, who bore the often devastating ancillary consequences of others' private bargains. In economic theory, a corollary to this view was detected in a recognition of the problem of 'social costs' passed to third parties – workers' families and communities – when wages were too low.

Corporate liberals, meanwhile, also imagined institutional mechanisms for achieving economic and social stabilization without extensive government control. Their key innovations involved extensive support for production of policy knowledge, such as work by Wesley Mitchell's National Bureau of Economic Research on business cycles. Herbert Hoover, as

Commerce Secretary and President, backed off on antitrust prosecutions while promoting voluntary trade associations for promoting business cooperation. Rather than looking to assist workers through redistribution of income, the voluntarist, associative strategy here was to raise living standards by growing the economic pie.

Against this voluntarist current, statist progressives continued to look to independent unions protected by the state and to democratic politics as the means for achieving an 'economic republic' and an 'industrial democracy.' Their vision included political recognition of three inalienable rights of worker citizens – a 'living' wage sufficient to support a family in reasonable comfort, the right to organize collectively, and a labor voice in management – as well for some as a guarantee of employment. This earlier thrust is not always visible in histories of the U.S. welfare state.

The 'Turn' to Social Insurance

Underway in Europe much earlier, the new-liberal 'turn' to social insurance came in earnest in the U.S. case only in the second and third decades of the twentieth century. Rising in social work, social feminist, settlement, and bureaucratic circles, it signaled the onset of a second phase in new liberal thinking, running parallel, but in important respects contrary, to the older movement for achieving industrial democracy by empowering workers and regulating labor standards, thereby redistributing income. Several factors can be seen to have promoted adoption of a social insurance perspective, among them the arrival among educated elites of an environmentalist consensus on the causes of poverty and accumulating realism about distinctive constraints on labor's capacity to organize an independent political program within the U.S. version of non-ideological, coalition-based, patronage-dispensing political parties. As well, though increasing social tensions compelled American cities to provide some public relief during cyclical downturns from the 1870s forward, the expectation among many in the Protestant middle class that private charity should aid only the 'truly needy' remained strong.

In the rise of a compensatory approach through social provision, Atlantic-crossing academics with expert knowledge played a major role. Bismarckian introduction of several worker-appeasing social insurance programs through Great Britain's adoption in 1911 of broadly accessible unemployment insurance were faithfully cataloged in works such as Isaac Rubinow's *Social Insurance* (1913). As class conflict accelerated, inquiries staffed by social scientists, among them the famous Pittsburgh Survey (1907–08) and the United States Commission on Industrial Relations (USCIR, 1913–15), documented corporate abuses, the powerlessness of working class communities to combat them, and the toll exacted upon workers' families. To some thinkers these findings suggested a renewed drive for aggressive labor standards reform and protection for unions. Yet, contrary to the strong government role envisaged by the USCIR and in wartime programs for improving labor standards, in the post-World War I period, wartime wage codes and protections for collective bargaining were quickly dismantled, as government at all levels tolerated – even encouraged – an open shop movement based on individualist premises.

With Herbert Hoover in a prominent organizing role, the Wilson and Harding administrations arranged a series of high-level conferences for planning postwar stabilization concentrating initially on efforts to comprehend and moderate the business cycle. Allied with the President's Conference on Unemployment, Wesley Mitchell's National Bureau of Economic Research offered vital statistical work that suggested new policy options, among them enrichment of the informational climate for business decisions, accumulation of reserve funds for countercyclical public works at the local level, an actuarial approach to relieving unemployment through funds amassed by employers, unions, or government, and acceptance of state-level workers' compensation schemes, partly to avoid stricter employer liability enforcement. In what was clearly one of the most significant conceptual shifts in modern governance, these more conservative approaches transformed unemployment from a problem of the political order rooted in inequality into an insurable risk to be managed technocratically in the firm or industry.

But the impulse for what from the perspective of liberal-statist, laborist, and social-feminist proposals for extensive redistribution of income and political voice became a critical *retrenchment* in social policy thinking arose not only from these liberal corporatist initiatives, but from at least three other, at first glance unlikely sources as well: a maternalist turn in some of the women's movements of the long progressive era; negative visions of the immigrant poor propagated by the Chicago school of sociology most particularly; and the aggressive expansion of carefully targeted forms of social provision by the private sector, imagined as a strategy for making the 'modern manors' of welfare capitalism reliable instruments for securing the loyalty and uninterrupted productive service of industrial employees.

As politically conservative opposition to protective legislation extending the police powers accumulated and the suffrage crusade shifted to political mobilization, important segments of mainstream, middle-class feminism took on a more elitist, exclusionist cast, and a 'female dominion' of women's protective institutions increasingly followed a separate course in identifying reform goals. Leading female reformers built a case for special state-based income assistance to virtuous mothers and children and special provisions for safeguarding maternal and infant health. Thus maternalists helped to shape an American pattern that women's historians have identified as a 'two-channel welfare state.' By the 1930s one channel provided contribution-based coverage for male workers under comparatively generous income-replacing programs such as unemployment insurance and Social Security, whereas the other offered only meager, means-tested, minimally tax-funded 'welfare' for stay-at-home mothers and children, but little assistance of any kind for most female workers and people of color.

Against this trend toward the retreat to social insurance, two bastions of investigative activism in the national government continued to lobby for equal treatment for those workers. The wartime Women in Industry Service led by leftist Mary Van Kleeck, which became the U.S. Women's Bureau, sought gender equity on the job in war and peace. The short-lived Division of

Negro Economics (DNE) headed by National Urban League leader George Haynes aided the equitable integration of Southern Blacks into northern war work. Striving to 'integrate' the labor question, another group of mostly male social scientists and social investigators, Commons student Paul S. Taylor and New Deal artist Dorothea Lange among them, exposed equally pernicious myths about the needs and abilities of Mexican, Mexican American, and 'poor white' workers. Congress defunded DNE soon after the war and migrant workers, Hispanic as well as African American, remained (remain) vulnerable to endemic discrimination and periodic spells of outright persecution. In all these developments, social and economic investigation served a dual purpose: grounding public discussion in reliable information rather than what publicist Walter Lippmann termed 'pictures inside men's heads' and providing a basis for strategic and relatively safe advocacy.

Against the collectivist shadings of both statist and corporatist ideas, neoclassical economists cultivated statistical and mathematical models of analysis between the 1890s and the mid-twentieth century that extracted economic behavior from history and culture, (re)naturalized the workings of the market, and turned the discipline into a potent form of social engineering. Quantitative, behavioristic, and functionalist models vied with historicism and institutionalism in other social sciences as well, perhaps most visibly in two massive collaborative efforts in Hoover-era policy knowledge, *Recent Economic Changes* (1929) and *Recent Social Trends* (1933). The dominant sociological discourse of the 1920s, the 'Chicago School' established by Robert Park, W.I. Thomas, and their students at the University of Chicago, offered an alternative to the liberal-statist explanation for poverty and urban ills that took the form of a cultural theory of family and community 'disorganization.' Culminating with Gunnar Myrdal's *American Dilemma* (1944), this new cultural analysis of poverty separated the poor from the capitalist strategies that shaped their lives and rendered those historically constituted structures less visible. Noting the persistence of such tendencies helps to account for the distinctive pattern of U. S. state formation, and particularly welfare-state development, that students of social policy, often taking the more comprehensive European welfare states as the 'normal' path of history, have seen as tardy, insufficient, and incomplete.

When wartime controls on the economy were quickly abandoned, corporatism flourished in the United States during the Hoover era (as it did in different forms during the interwar period in Europe as well). The sociology of ethnic difference merged with developments in the new sciences of management to promote the refinement of corporation-based programs for linking carefully constructed forms of social provision to employment with specific employers, which served as well as a guarantee against worker turnover. As arts of advertising based on a new consumer psychology legitimized the desire for attractive and plentiful goods, theories of an administered market allowed liberal corporatists to proffer a new economy of mass consumption as a palatable alternative to nineteenth-century producerist dreams of worker control and to aspirations for distributive equity envisaged in the ideal of industrial democracy.

Resisting this trend only formally as they accommodated skilled worker unionism to the realities of class power, the American Federation of Labor assented to the views of industrial relations experts who were constructing a new profession in the 1920s in recognizing productivity increases, and not older republican-based claims for more equitable distribution to producers, as the sole and indispensable basis for increases in wages. Where company welfare programs existed in the 1920s, worker loyalties based on them ran quite deep, particularly in ethnic communities often played off against each other on the job. Thus the sudden collapse of welfare capitalist programs, the weak Hooverian response to the Great Depression crisis, the welcome proliferation of New Deal programs targeting unemployment, and the aggressive organizing efforts finally unleashed by national labor-rights legislation helped to ratchet up workers' expectations for the role of government. Pulling in long-time statist-leaning new liberals and their ideas, and despite early New Deal liberal corporatist tendencies, Franklin Roosevelt's turn to a class-edged defense of entitlement to jobs and to expanded social insurance programs reinvigorated impulses, largely quiescent since the immediate postwar World War I era, toward the development within government of planning capacities capable of heading off such emergencies in the future, and of democratizing both industrial governance and the political state.

The Limits of Liberal Statism

The broader vision of a deliberative process that could detect and shape the impact of American capitalism on society was the unifying insight at work in the planning agencies of the New Deal, most evident in the activities and discourses of the Public Works Administration, the National Resources Planning Board (NRPB), the Committee on Economic Security (CES) that devised alternative blueprints for Social Security, and the Temporary National Economic Committee (TNEC) that investigated how far monopoly had presaged or extended the Great Depression.

The so-called 'planning impulse' had a long history. In the 1910s as a conservationists' discourse of efficient natural resource management and in the 1920s often as a welfare corporatists' discourse it had drawn comparatively little fire. Stressing continuities in the development of a national planning capacity that bridged private and public, even the early New Deal National Recovery and Agricultural Adjustment Acts could seem like little more than continuations of corporatist strategies for controlling the volume of production through a beneficial collusion among competing producers to sustain prices, now under the cover of state compulsion.

Yet a parallel, consciously statist movement also appeared in the early 1930s, fueled by FDR's determination to create both government and private sector jobs to reduce catastrophic and politically unacceptable unemployment not amenable to associative solutions. Voices farther to the left demanded full utilization of idle resources and full employment of labor, strengthening the hands of New Dealers, brought to Washington in the hundreds, who were determined not to waste a crisis. Recruitment to government planning agencies of eminent social scientists, including a large number of historical

and institutional economists, energized and updated the liberal statist strand of new liberal thinking. By the mid-1930s policy innovations shifted the planning discourse toward using resources more efficiently over the longer term, expanding public infrastructure investment, rekindling demand, and supplementary job creation – policy goals institutionalists insisted would promote economic stability and distributive equity. The National Labor Relations Board in 1935 framed its mission in these terms, contending that ensuring workers' rights to organize independently equipped trade unions to play a role in redistributing income, thus supporting the workers' ability to consume while democratizing industry.

Economists' knowledge and planners' leanings toward infusing market structures with civic purposes also blended in agencies such as the venerable Bureau of Agricultural Economics and the community-building oriented though ultimately disappointing Tennessee Valley Authority. The Farm Security Administration addressed the issue of chronic farm surpluses, but also the economic and social marginality of people at the bottom of rural hierarchies who were unable, without the kinds of government assistance long ago advocated by 1890s Populists, either to synchronize production with world-market demand or to retain enough income from their crops to live decently. For the manufacturing sector, a major study of the concentration of economic power steered by Thurman Arnold and Leon Henderson for the TNEC referred the failure of prices to decline along with wages and the slow pace of investment in new industries back to the monopoly power that allowed large corporations to administer markets. An analysis of the 'stickiness of prices' by Gardiner Means of the NRPB on the basis of extensive study of investment and pricing patterns pointed in the same direction.

The meaning of planning was shifted most decisively by theoretical, institutional, and practical innovations generated by the NRPB, as Roosevelt enlarged that New Deal agency's role to guiding government efforts to achieve recovery and later to maintaining prosperity at war's end. A body of economic knowledge cobbled together in the early 1930s by economists such as Edward Chamberlain, Joan Robinson, Alvin Hansen, John Maynard Keynes, and Michael Kalecki explained how equilibrium well below the level of full employment of labor and capital had been reached and sustained over nearly a decade. Building upon this analysis, economists at NRPB and the Federal Reserve zeroed in on underconsumption as a factor in the slow, uneven pace of recovery, discovered the 'multiplier effect' of government spending, and insisted that gains could be achieved by more aggressive deficit financing of public expenditures in the form of worthwhile civil works.

By the definition of planning that flowed from this new thinking, the state became minimally responsible for continuously monitoring and occasionally augmenting or shifting investment flows in socially constructive directions not attractive to the private capital markets and for supporting incomes to support consumption. Inside the CES, one faction of planners insisted on continuing provision for government-subsidized full employment, but the victorious vision tilted more toward social insurance through an expanding welfare state. Among advanced elaborations of New Deal liberal statism, a report titled *Security, Work, and Relief Policies* (1942) conveyed NRPB's synthesis of three related but discrete government roles: financing and extending social insurance to care for those unable to participate in the work economy, guaranteeing work for the segment of the population securely attached to the labor market, and underwriting a still highly contested version of industrial democracy through defending the self-organization of labor. Through its promotion of this triad, the NRPB enunciated a moderately statist vision of a new social contract – one that, notably, did not include a civil rights dimension, reflecting not only FDR's and the New Deal's unwillingness to risk losing Southern Democratic votes but, as well, a more general silence on the race question among new liberals going back to the 1880s.

Though more credit has been given New Deal planners in light of post-1970s attempts to roll back New Deal reform, they managed only a partial and temporary fulfillment of the moralizing role that early liberal statists had charted for knowledge-based civic discourse. The Fair Labor Standards Act of 1938, which established a 40-h work week with time-and-a-half for overtime work, set a national minimum wage, and banned most child labor, was perhaps the apogee of labor standards reform; yet it exempted many members of the working class – most women, farm workers, domestic and managerial employees – from its protections. The Fair Employment Practices Commission also largely failed to address racial and gender discrimination.

Even so, opposed by antistatists, the NRPB's interest in postwar planning was one of the factors that led to the uncer-emonious termination of the agency by Congress in 1943. The silencing of NRPB was a milestone in the history of new liberalism and of the social sciences as well. The commitment of New Deal planners to full employment proved untenable in the face of rising opposition to the New Deal. Thus the Council of Economic Advisers created by the watered-down Employment Act of 1946 lacked the authority to trigger government spending at a level needed to achieve full employment, though the agency continued at least through the Truman era to press for a key government role in the postwar expansion of the economy, to jawbone against monopoly as an obstacle to growth, and to press for fuller socialization of the insecurities of modern living.

The Containment of Liberal Statism

Whereas statist elements of New Deal reform met with powerful opposition by the late 1930s, the rudimentary modernization theory embodied in Hoover's associative state was further elaborated during the Cold War, as U.S. manufacturing and credit extension underpinned the non-Soviet world economy. The need for uninterrupted production to reap the profits from rising demand formed the basis for a kind of truce between capital and strong industrial unions based on supervised collective bargaining, negotiated wage adjustments to meet inflation, a union crackdown on wildcat job actions, and elite theories that cast this system as the start of a 'post-capitalist' era of widespread abundance. Although President Dwight Eisenhower cautioned against the dangers of a 'military–industrial complex,' U.S. foreign policy dictated massive defense production alongside consumer goods manufacture, leading to low unemployment rates and good

wages. During the immediate post-World War II era, a mildly redistributive welfare state expansion including the GI Bill, social security extension, and minimum wage protection expressed an ongoing progressive commitment to some measure of social and economic democracy – though for whites only. Failed proposals for universal health care and full employment traced its limits.

The architects of U.S. corporate liberalism never intended it to become a European-style corporatism that involved mandatory codetermination of industrial and labor policy; in the diluted native form, it provided an alternative vision to liberal statism, supplying a degree of constraint on both income-supporting policies and union participation in economic planning that was present in anything like comparable strength nowhere else. More than other distinctive U.S. features, the fuller elaboration of the associative vision even during the deceptively radical 1960s goes far to explain both the special character of modern United States liberalism and the persistence of powerful linkages between ruling business elites and pro-corporate antistatists in political roles.

In light of recent scholarship, we now know much more about the mobilization against the New Deal, including how vehemently anti-New Dealers worked to defeat government planning for economic performance. Opponents of planning clustered around nodes represented by the resurgent free market liberalism of Friedrich von Hayek, who forecast a long slide down the slippery slope to communism for welfare states, by the romanticized heroics of libertarian novelist Ayn Rand's fictional entrepreneurs, and by concerns among business conservatives and Southern industrialists that federal government 'interference' might invade local prerogatives regarding labor organization and race. Aiding their project, a 'fiscal revolution' in economic policy thinking, underway by 1937 and dominant by the 1960s, offered modified, 'commercial Keynesian' policy knowledge suggesting that the measured use of fiscal and monetary levers would enable macroeconomic stabilization without requiring intrusion into capitalist investment practices or extensive interference with labor markets. Those who took this view in the early postwar decades typically saw some benefit in the collective bargaining structures mandated by the National Labor Relations Board (NLRB), whereas they preferred that all decisions regarding production be left to private ordering in the context of a mildly redistributive compensatory state.

Even more important foes of liberal statism were organizations where conservative theorists and high-level business executives engaged in counter-planning against all that the New Deal had inaugurated for the role of government. These efforts began quite early as business conservatives organized in the Liberty League, the National Association of Manufacturers, and the Chamber of Commerce to promote a pro-business agenda against labor unions and Social Security, and to finance economists such as Hayek, who organized the laissez-faire oriented Mount Pelerin Society in 1947. Against his own preference, this organization abandoned reservations about the moral exactions of modern capitalism that remained urgent for conservatives such as Hayek and early Chicago-school economist Frank H. Knight. The economists' laissez-faire movement, linked with anti-communism through the John Birch Society and informed by center-right economic theory through the Brookings Institution and the American Enterprise Institute, found a champion in staunchly anti-New Deal and pro-states rights department store magnate Barry Goldwater in his Phoenix-centered mobilization of business conservatives. Although his 1960 election campaign demonstrated the perils of attacking Social Security, it also set the stage for pro-market conservatives to turn the Republican Party into a vehicle for anti-statist ideology.

To sum up, whereas the first generation of American liberal-statist social scientists had reconstituted government as a knowledgeable, capable, morally responsible regulator and redistributor, and the second generation had modeled the state as social insurer and mediator of class antagonisms, the third, late New Deal generation of statist liberals conceived a state role that captured the planning role that originated in the conservation movement, the social provision role embodied in the Beveridge Plan, and the codetermination methods that took hold in postwar European social capitalism. It was strongly nationalist, and thus reminiscent of older Hamiltonian and Whig models of a development state responsible for energizing and supporting through provision of infrastructure voluntary community efforts leading to balanced economic, moral, and civic development of the commonwealth. Policy discourses of the 1950s, developed around Cold War internal security issues, an increasingly consensual commercial Keynesianism, modernization theories exported from the United States as technologies for liberal internationalism, dreams of 'post-modernity' in social relations, and domestic discourses of racial and gender identity, challenged the normative postures that liberal statists and left progressives had formulated between the 1880s and the Fair Deal and inaugurated a new ideological era. The legacy remains, embodied in resilient structures of disciplinary knowledge formation, though once durable discursive norms that demanded grounding political argument in social empiricism have been dramatically compromised in the post-1970s era of 'take no prisoners' partisanship that moved the U.S. political spectrum dramatically to the right. Still, absent the polarizing tendencies of a world divided between capitalism and state communism, and even given now the resurgence over recent decades of libertarianism and free market ideology, it becomes ever more obvious that the critical decisions in democratic governance in the West, and beyond, will henceforth be – as they were in the new liberal era, 1880s to 1940s – hard choices between variants of modern liberalism.

Policy Knowledge: Universities

Michael Hoelscher, Universität Heidelberg, Heidelberg, Germany

This article is a revision of the previous edition article by D. Court, volume 17, pp. 11605–11608, © 2001, Elsevier Ltd.

Abstract

In the knowledge society, political decisions increasingly have to be based on scientific results to be seen as legitimate. Governments increasingly hold universities accountable for providing such applicable knowledge. The article analyses (1) the current context, (2) the setup of this policy–research nexus, as well as (3) its epistemic impact on legitimate knowledge within science, and (4) the organizational consequences for universities and the social and behavioral sciences. One conclusion is that an increased openness toward policy-relevant issues has to be combined with research's independence from external influences to secure one of its most important contributions, namely a legitimate critical reflection on policy and society.

Introduction

One of the few unambiguously perceived trends of modern societies is the growing importance of knowledge, often described as the emergence of a knowledge society or knowledge economy. This process of scientification is defined by Weingart as "a process whereby the use of and claim to systematic and certified knowledge produced in the spirit of 'truth-seeking' science becomes the chief legitimating source for activity in virtually all other functional subsystems" (Weingart, 1997: 610). One of these subsystems is the political realm. Political decisions are, and have to be to gain legitimacy, increasingly based on scientific knowledge. However, this also has important repercussions for academia as the most important producer of this kind of knowledge (e.g., Boaz et al., 2008). While universities always generated useful and applicable knowledge as well as graduates well prepared for jobs in government, the administration, and the labor market more generally, current developments put much more pressure on higher education institutions to produce 'value for money.' Changes in the mode of knowledge distribution in the past decades, characterized by a smooth shift from supply- to demand-led knowledge production, resulted in a substitution, or at least complementation, of universities' traditionally claimed autonomy by a growing accountability toward the needs of government, society, and economy.

The following paragraphs will analyze the research–policy linkages from two perspectives and on two levels. First, looking outward, it will ask what kind of knowledge is needed in the policy realm and how it is transferred from academia into the policy realm. Looking inward, it will describe some implications of an increasingly demand-driven knowledge regime for the social and behavioral sciences.

At least as important as the growing dependence of political decisions on scientific knowledge is, second, a resulting growing demand for scientific literacy of citizens. Therefore, the topic of 'policy knowledge: universities' not only is understood as knowledge that is produced within universities and then used by governments to formulate policies but also incorporates the university-taught knowledge needed by responsible citizens to critically evaluate these policies. Taking this viewpoint results in two different levels of analysis within universities and their generation of policy-relevant knowledge: research and teaching (see **Figure 1**).

The structure of the article is as follows: In a first step, the relevant political and social context for today's universities is outlined. The next two sections discuss the implications of these trends for appropriate forms of knowledge and for the organizational setup of universities. The Section The Transfer of Knowledge from Universities into the Policy Realm discusses how knowledge is transferred between universities and policy. Then the Section Implications for the Social and Behavioral Sciences outlines some potential implications for the social and behavioral sciences. Finally the article ends with some conclusions and an outlook.

Before describing the current context, though, one caveat has to be mentioned. The situation is very heterogeneous across the world. However, this article is concentrating on the (though still very heterogeneous) situation in the developed countries, mainly from the OECD.

Figure 1 A model of knowledge transfer.

The Political and Social Context for Universities in the Twenty-First Century

Although universities as one of the oldest still existing institutions worldwide have always followed their own logic to some extent, they also have been influenced by their social, political, and economic contexts through the centuries. This paragraph outlines some transnational trends that are of special importance to the relationship between policy and universities, while acknowledging that national and regional developments are also relevant. Consequences of these trends will be discussed in the following sections of this article.

One of the most important developments is the worldwide expansion of participation in higher education during the past decades (Schofer and Meyer, 2005), turning universities from elite- to mass institutions (Trow, 1972) in many countries. This results in a need for additional funding and more generally in an increased importance of university's role in society.

Another important trend is the emergence of what is often called the 'knowledge society' or 'knowledge economy' (Delanty, 2001). Interestingly, this trend was also made popular by Bell's "The coming of post-industrial society" (1973) at the same time as Trow published his observations on expansion in higher education. Within the economy, knowledge has become ever more important, and at least in the developed countries it is sometimes seen as the dominant means of production, as increasingly industrial production sites are moved to countries with cheaper labor costs. Within modern societies, the process of constant 'rationalization,' as already described by Max Weber, calls for ever more information as the basis for decision-making on different levels (national, organizational, individual). Especially the political realm calls for information to legitimate and justify its decisions, so that it is able to deliver what is often called evidence-based policy-making. Universities contribute to this in two ways: by producing 'human capital' through educating students and by producing new knowledge through their research function (e.g., Jasanoff, 1990).

Globalization is a third trend influencing universities (Hoelscher, 2012; Scott, 1998). Growing flows of money, goods, people, and ideas across national borders open up opportunities, but also put pressure on higher education institutions. Eased exchange of ideas and researchers allows for transnational learning processes and creative innovations. However, as a corollary of globalization, one also finds increased competition and market orientation in the field of research and education (Slaughter and Rhoades, 2004).

These three trends are probably the most important reasons for an increased interest of policy in universities as well as academia's "expansion of interest in policy and application," mentioned already in the introduction to the first edition of this Encyclopedia: National governments as well as international organizations today see universities, main providers of human capital and of research-based innovation, as crucial for establishing or keeping a good position in the international economic competition. As a result, governments increasingly call on universities to provide the means to this end, with implications for the organizational setup of universities as well as for the appropriate forms of knowledge (e.g., Pawson, 2006: 2).

Implications for Appropriate Forms of Knowledge

Academics in many universities increasingly feel a pressure to produce directly applicable knowledge and educate graduates with regard to the labor market, and many criticize this as political and economic appropriation and exploitation of academia. Instead, they endorse the disinterested pursuit of truth and knowledge and claim that the academic freedom, whose basis was already laid out to some extent in the *Authentica Habita* as early as 1155 and which, for example, in Germany until today is guaranteed in the Basic Constitutional Law, is a necessary prerequisite of scientific progress as well as the basis for the critical engagement with existing social norms and values. Additionally, independence and autonomy of teaching in higher education is seen as important contribution to democracy and consequently as civil right (Dahrendorf, 1965).

While these critics are probably right in many points, one has to keep in mind that universities always educated their graduates to be able to fill their positions in society (Rüegg, 1992–2011). Already in the Middle Ages, the universities trained their graduates in the traditional fields of philosophy, theology, medicine, and law for certain professions. While the traditional task of the university was to preserve the culture and knowledge by passing it on to future generations, the modern university with a strong focus on research and innovation, which was until then often concentrated in the academies, began to evolve only in the eighteenth century and became extremely successful in many countries during the nineteenth century. This went along with a differentiation of taught disciplines. In this context the foundation of empirical social sciences was mainly based in the need of the modern state to acquire in-depth knowledge of its citizens. More recently, still, many institutions took social problems as their starting point for their successful and inspiring research, for example, the Chicago School of urban sociology.

Two founders of the modern idea of the university, Humboldt and Newman, both had occupational positions, especially positions that one could label as policy related, in mind when formulating their (different) approaches: Humboldt wanted the university to train independent scholars by promoting the unity of research and teaching, as he was convinced that such scholars were best prepared to later become civil servants for the Prussian State. For Newman, universities' task was to educate (then only) Gentlemen to become future leaders within the Commonwealth. The interesting twist, however, is, that both saw more or less independence of universities from the state/church, the teaching of nonvocational subjects and the fostering of a liberal intellectual culture as the best way to reach these aims. At least since the end of the Second World War, and additionally fostered through the student revolts during the 1960s, the idea of the university was crucially based on this dual task of independent research on relevant societal problems and the education of knowledgeable and critical-reflexive citizens. But how do the developments described above impact on the research and teaching function of higher education?

With regard to teaching, the expansion of higher education participation has raised questions of skills, competencies, and

knowledge needed for being successful in the labor market. While citizenship education is still an explicit aim at least in some countries, there is a tendency in many countries to make curricula much more directly applicable and in line with the demands of employers. The European Bologna Reform of Higher Education is an often criticized example for this shift. A possible reaction to this pressure is a diversification of higher education systems, with a top layer of universities still following the traditional ideal and a majority of higher education institutions educating more or less applied subjects preparing their graduates directly for the labor market. However, at least with regard to policy knowledge, it is still debated whether such knowledge can be directly taught in an applied way, or if it does not need to be carefully developed through fostering reflexive and contextual thinking, as was the aim in the traditional university. This refers to the broader discussion of a distinction between experts, solving specific problems through the narrow application of scientific knowledge, and intellectuals, developing larger meta-narratives and even utopian thinking and interpreting society and the world through these lenses (already Chomsky, 1967; Merton, 1945).

With regard to research, especially the rise of the knowledge society has led to the formulation of new requirements for larger parts of scientific knowledge production, which go beyond the divide between applied and basic research. One prominent concept in this context, covering the most important aspects of this shift, is called Mode 2 knowledge (Gibbons et al., 1994). In a critical review, Weingart points out the following aspects as being central for proponents of the approach: Knowledge is seen as becoming increasingly problem based and has to be produced within concrete contexts of application. As these complex problems and contexts cannot be grasped by one scientific discipline alone, research has to be transdisciplinary. Additionally, the research output and results not only are evaluated by scientific peers within academia any more but also have to convince those actors that are involved in the specific problem or situation. Thereby, "knowledge-production becomes socially accountable and reflexive" and "comes under new pressures of legitimation" (Weingart, 1997: 593).

While the concept of Mode 2 knowledge production has been criticized for being exaggerated, it highlights important current trends with interesting epistemic implications. Mode 2 is as much about practical knowledge (techné/τέχνη in Aristotle's terminology) as about theoretical knowledge (episteme/ἐπιστῆμη), and even includes aspects of beliefs and opinions (doxa/δόξα) as well as, at least in the case of social sciences, wisdom or intelligence (phronesis/φρόνησις) (e.g., Flyvbjerg, 2001). Scientific results increasingly do not only have to pass the critical assessment of the academic community but also shall prove their applicability and usefulness in domains outside science and for nonscientific audiences. This might, however, result in tensions, when for example public policy and business pose differing demands on university research. One possible reason for this might be that exploitation interests of economic actors collide with society's interest in public availability of research results. A prominent example from the natural sciences was the race to decipher the human genome.

Implications for the Organizational Setup of Universities

The stress on knowledge and innovation by governments and in society at large and the subsequent changes in the forms of knowledge and its production also have an impact on the setup of universities.

As described, the increased need for scientifically based knowledge in different parts of society, as well as increased funding for the higher education sector, results in an enhanced demand for accountability of universities by different stakeholders (Benneworth and Jongbloed, 2010). With regard to policy knowledge and the social and behavioral sciences, these stakeholders mainly stem from the political realm or civil society, but also actors from the economy are involved to a growing extent, for example, in the context of technology assessments and forecasting.

On the macro level, increased accountability in many countries is just the other side of a growing (formal) autonomy of higher education institutions from the state as a result of a strange mixture of neoliberal ideology and New-Public-Management-thinking on the side of governments, and efforts to gain independence on the side of the universities (Lazzeretti and Tavoletti, 2006). The idea behind this is that universities need additional freedom to be able to partake successfully in the global competition for the best students, the best researchers, and the best innovations. This increased competition between higher education institutions on the national and international level has led to what is often called the 'Entrepreneurial university' (Clark, 1998).

One example is the distribution of additional money for research, which is increasingly project driven, allowing the government and other funders to define research topics and goals (Harman, 2010). While government funding for research in higher education and other public research institutions remained on average pretty stable at around 0.6% of GDP between 1981 and 2000 for all OECD countries, especially larger countries experienced a substantial decline (OECD, 2003: 78). Additionally, one can observe an internationally visible shift from institutional (block grants) toward project funding (especially during the 1970s and 1980s), and within project funding from academic-oriented instruments toward thematic-oriented instruments (Lepori et al., 2007). This probably leads to a greater applicability of research results. Within the context of the currently very tight budgets, there is however the danger of a certain blindness, so that research only looks at problems relevant for these funders, and that at the same time equally relevant problems of less financially potent parts of society are neglected. Therefore, it is still an open question whether the two sides of the coin, increased autonomy and accountability, actually increase the independence of academia, or if this results in new, maybe even more binding dependencies.

Increased accountability has been implemented inter alia through different means of steering universities, for example, through evaluations or the introduction of quality assurance and management programs (Danish Evaluation Institute, 2003). With regard to state funding, one can observe a shift from input to output measures. For example, university budgets are often no longer assessed on the basis of numbers of

students and scientists, but on the basis of graduates and the number of publications.

Another important development on the macro level is the growing importance of additional knowledge providers besides the traditional universities, such as think tanks, NGOs, government agencies, or consulting firms. Their absolute number is negligible compared with universities, but they are gaining influence and visibility, especially in the field of policy knowledge. While they are often still dependent on the research input from universities, their advantages are a better transfer of knowledge into the policy realm and often their clear ideological position. As an effect, they might buffer universities from too strong claims for production of applicable policy knowledge, but they might also detract important research resources from them.

On the organizational meso level a 'third mission' for universities besides teaching and research has been formulated as a consequence of the described shifts. This third mission sees active engagement of universities in transferring knowledge into society as an important task (Zomer and Benneworth, 2011). Universities are creating specific facilities to promote patenting or research collaboration with external partners, mainly relevant for the natural and engineering sciences and medicine (where they are often called 'technology transfer offices'), but they are also trying to establish new forms of collaboration for the social and behavioral sciences, such as engagement in public science.

Another important development at the university level is the establishment of inter- or even transdisciplinary centers besides the traditional departments based on scientific disciplines. With this reaction to the shift toward what was called Mode 2 knowledge production above, ever more universities establish problem-oriented centers, which are often built around policy-relevant topics, such as the 'Heidelberg Center for the Environment,' and frequently include external funding, for example, like the 'INET@Oxford' with money from a New York-based nonprofit foundation. Another important characteristic is the common collaboration between researchers from the social and behavioral sciences and researchers from the natural and life sciences.

On the micro level of the single researcher, the developments lead to important tensions that have to be solved creatively. As academia is still mainly organized along the traditional disciplinary lines, it is rational for each researcher trying to follow an academic career to become a specialist in her field and to orient his research toward inner-scientific research problems, as it is still difficult to publish applied research results with the best journals. On the other hand, the additional efforts needed to establish cooperation with partners from outside the university and to get engaged with the 'real' world, sometimes on the expense of scientific rigor, could result in increased funding. While there are always people on both extremes of these dimensions, handling this balancing act might secure certain academic standards for applied research in most cases. However, increased competition and a growing dependence on external research funding present the danger that applied research results are more and more aligned with the expectations of the external funders. This, in turn, would decrease the utility of this kind of knowledge to policy, as it would be unreliable and therefore potentially misleading.

In general, one can observe growing diversification within universities as well as within whole higher education systems. The shift toward a knowledge economy and toward growing competition between and within institutions has led to very different reactions on the various levels of academia. While the above-described trends toward more accountability, Mode 2 knowledge and interdisciplinary cooperation are an important facet of current developments, at the same time a growing specialization within disciplinary fields and a concentration on inner scientific quality measures can be observed. Interestingly, it seems that those institutions with the highest academic prestige also possess the highest reputation in the policy realm. Whether this is because of their superior performance or due to the seemingly larger legitimacy they give to policies supported by them, as many sociological neoinstitutionalists would argue, cannot be decided here.

The Transfer of Knowledge from Universities into the Policy Realm

A growing interest for scientific knowledge in the policy realm and a growing awareness of such a demand within the universities is, however, not enough to guarantee successful knowledge transfer.

A general problem for the research–policy nexus is that scientific knowledge is always to a certain extent preliminary. Following Karl Popper, science is a constant process that is not able to prove or verify a natural law, let alone other theories and hypotheses, finally. Researchers can only make their theories stronger by trying to test or falsify them and being unsuccessful in this endeavor. Additionally, Thomas Kuhn has shown how different paradigms within science replace each other. The current need to base political decisions on the newest research available to secure the legitimacy of these decisions has the paradoxical effect that the research findings are often still controversial: "The ever more intense recourse to knowledge on which to base decisions also reveals ever more clearly the state of ignorance" (Weingart, 1997: 606). As a result, policy can neither wait nor expect final words of wisdom from academia. This is not to say that scientific knowledge is always relative and cannot claim high validity. However, especially with regard to very new and very complex topics, there is always a certain uncertainty, which leaves room for discussion and even abuse (e.g., Collingridge and Reeve, 1986), a situation sometimes labeled as *postnormal science* (Funtowicz and Ravetz, 1993). This makes the reliance of policy-making on scientific knowledge, while necessary, for politicians and their advisors quite risky and difficult.

An interesting example of such an abuse is the renouncement of anthropogenic climate change. While a seldom found consensus within scientific research on the topic states that climate change can be traced back to human influences (see the IPCC as a representative of this consensus), financially potent interest groups successfully block political decisions by claiming the incertitude of these findings under a scientific disguise (e.g., McCright and Dunlap, 2010).

With regard to social and behavioral sciences, the reflexive reactivity of its research objects is another problem for a smooth knowledge transfer from these disciplines into the

policy realm. While the weather does not change due to weather forecasts, a prognosis that many people will die because of obesity might lead to a change in peoples' eating behavior, in the provision of food by the economy, and in the political framework, thereby refuting the original prediction.

Besides such general problems, different contextual factors can hamper or foster policy–research linkages in a more direct way. These can be categorized into three streams of explanation: supply-side accounts, demand-led explanations, and sociopolitical thinking on knowledge utilization (Maxwell and Stone, 2005: 2 ff.). Important factors on the supply side might be, for example, the lack of a proper research infrastructure in the first place, a missing interest of researchers in transferable and policy-relevant knowledge, or an absent awareness of research output's potential usefulness. Corresponding factors on the demand side might be ignorance of politicians with regard to the existence of such knowledge, or an incapability or even the missing preparedness to use such knowledge to inform policy. The category of sociopolitical thinking comprises different aspects, for example, questions of who the 'user' is, on how valid and reliable the knowledge actually is, and on what can be known anyway. Illuminative in this last respect are discussions around what has been labeled as 'Science wars' (Flyvbjerg, 2001: 1 ff.).

Broadly one can differentiate between at least three channels through which knowledge can flow from universities into the policy realm: the first is depersonalized information in the form of research reports, and so on, the second are organizations, and the third are individuals. The depersonalized transfer of information seems to be pretty straightforward at first sight, but has some prerequisites. First, with reference to the just mentioned factors on the supply side, the relevant information has to be supplied, and supplied in a way that is understandable for the policy side. In recent years, a growing share of research projects has become aware of this and produces policy-related research briefings on top of their normal research reports.

On the policy side some receptor units able to absorb the scientific information and make it available for politicians are needed. Government agencies, ministries, and parties are establishing smaller research units to fulfill this function. Additional intermediary organizations would be the already mentioned think tanks.

With regard to people, one can further differentiate between graduates starting a job for example in a governmental organization, established scientists moving from university into the political sphere, and politicians or civil servants joining academia for a certain period of time. The state is still one of the most important employers for higher education graduates in many countries overall, and holding a university degree increasingly becomes a prerequisite for joining the political elite, as is the case with economic elites. To foster knowledge transfer through this channel, it is important to equip these graduates with research-based, and therefore most up-to-date knowledge in their fields of study, to teach them how to apply this knowledge in praxis, and to engage them in lifelong learning. In some countries, certain academic institutions are especially successful in placing their graduates in high political positions (or rather people with such ambitions choose these institutions). For example, 6 out of the last 10 presidents of the United States hold a degree from either Yale or Harvard, and 8 out of the 11 British Prime Ministers since 1945 studied at Oxford University. It is obvious from these figures that certain academic institutions are better positioned for knowledge transfer than others.

The exchange of personnel is another mechanism for knowledge transfer well known from innovation studies. However, the amount of exchange between the political and the academic realm differs widely, depending on the openness of the two systems and the attractiveness of such a change for the individuals. In many cases, the exchange is not organized through a radical shift from one realm to the other, but through cooperation or cooptation, for example, in advisory boards. However, again large national differences exist.

There are certain advantages of the knowledge transfer through people over the mere exchange of information. The exchange of people results in an overlap of the two realms, opening up the opportunity for longer term cooperation as well as an easier flow of knowledge in both directions, both helping to "create[…] common understandings and identities" (Maxwell and Stone, 2005: 5). Additionally, there is a tacit dimension to knowledge, which cannot easily be transferred into formal information (Polanyi, 1967).

Implications for the Social and Behavioral Sciences

The current trends offer opportunities as well as threats for the social and behavioral sciences. The older democratic mass university was the *natural realm* of the social and behavioral sciences (Delanty, 2001). However, most of these disciplines lost importance in the entrepreneurial university since the 1980s, as the natural and engineering sciences are easier applicable and easier to commodify (Zomer and Benneworth, 2011). Keywords would be patenting, the emergence of science parks, or the cooperation with economically potent partners from the industry more generally. The social benefits of social and behavioral sciences' research are often much more diffuse and less visible, especially when the valorization of knowledge is narrowly understood in monetary terms. In many universities, social and behavioral sciences are therefore under pressure to prove their usefulness vis-à-vis the natural and engineering sciences. However, to restrict the social and behavioral sciences to a mere mechanistic problem-solving science, trying to imitate the harder sciences, is probably no option. Much of social and behavioral sciences' research refers to questions of values, power, and culture. To increase its impact, it has to develop a reflexive and dialogical approach, nevertheless based on sound and reliable empirical research, thereby contributing to "society's capacity for value-rational deliberation and action" (Flyvbjerg, 2001: 167).

The current situation offers many opportunities for this road. The knowledge produced by social and behavioral sciences is needed in the reflexive modernity more than ever: For example, many of today's societal problems, such as the aging of populations, migration, growing inequality, or environmental pollution, cannot be solved by merely technical solutions. Governments and international organizations have reacted to this for example by funding or even

initiating new large-scale data projects in the past few years (e.g., the European Social Survey or the PISA studies) or by supporting the development of new and more comprehensive indicators, for example, for well-being, complementing traditional measures (e.g., the Gross Domestic Product). Additionally, possibilities for the application of scientific innovations (e.g., genetic engineering; nanotechnology, the Internet) have to be analyzed with regard to their wider societal contexts and ramifications. The growing opportunities for interdisciplinary work within universities allows to account for social and behavioral sciences' theoretical and methodological tools to approach these and other pressing problems. However, this demands an openness or even the positive will to collaborate with other disciplines as well as with people from outside academia.

A severe problem, though, is the ongoing shift toward project-driven funding, as much of it is exclusively related to issues stemming from outside academia and affirmative in perspective. There is the threat that the social and behavioral sciences increasingly only contribute to effective technocratic interventions to problems formulated by others, instead of questioning the aims of these others. However, social and behavioral sciences need capacities to criticize the state, the economy, and society effectively and search for alternatives, as this is part and parcel of its task of applied research and positive impact.

Some Conclusions and Outlook

In the emerging knowledge society, political decisions increasingly have to be based on scientific results to be seen as legitimate. This has led to a shift from a supply to a demand-driven knowledge production. Governments and society at large increasingly hold universities accountable for providing such applicable knowledge. With regard to organizational consequences, these trends are often discussed under the label of universities' third mission, referring to the universities' preparedness of transferring their knowledge into different realms of society. The concept of Mode 2 knowledge production, instead, emphasizes more the epistemic changes within what is seen as useful scientific knowledge. Research, it is claimed, has to become more interdisciplinary, problem-centered, contextualized, and assessed by practitioners from the field of application.

This calls for improved ways of knowledge transfer between the realms of academia and policy. Researchers and universities as a whole are increasingly aware that they have to prepare their findings in ways that are accessible not only to peer academics, but to the broader society, the media, politicians, and the economy. Political organizations, on the other hand, have developed different means, such as own smaller research units, that are able to absorb these informations. Besides this exchange of information, the exchange of personnel is a much more direct way of knowledge transfer from one realm to the other. In most countries, one can find a growing number of additional organizations, for example, think tanks, moderating and influencing this transfer.

The processes of a 'politicization of science' (Weingart, 1997: 606) and of a 'scientification of policy' are probably self-reinforcing, especially under the condition of ever more citizens holding a higher education degree, making them ever more literate with regard to scientific findings.

This situation opens up opportunities as well as risks for the social and behavioral sciences and the university as a whole. With regard to impact, an opportunity is that it allows science to become more influential than ever. However, a crucial question here is whether political decisions are really based on the state of the art of scientific knowledge, or if the latter is just selectively used to legitimize the former. Science and its research findings are always preliminary. This insecurity makes it difficult for researchers to develop clear guidelines, and for politicians to use research findings in a straightforward way. Additionally, political decisions gain legitimacy from different sources, for example, from voters' demands, and often have to be a compromise with regard to different claims (and research findings). Actually, providing solutions to diverging claims is one of the key tasks of policy. All these put the direct policy impact of research into perspective. Nevertheless, in sum the increase of educated citizens, the rationalization of the world and growing research capacities will probably increase the reliance of policy on research and science in the decades to come remarkably.

A risk for university and science is the loss of its traditional autonomy due to political demands for knowledge. Important proponents of the idea of a university, such as Wilhelm von Humboldt in Germany or John Henry Newman in the United Kingdom, have unambiguously argued that universities can best fulfill their functions when they are independent from state, church, and other influences. The current increase in project funding in most established higher education systems can be seen as a sign of decreasing autonomy. In many developing countries, however, governments deliberately found new universities to provide expertise as well as experts for the administration.

Another big risk is a narrow commodification of research. If research will be confined to those aspects that pay off in monetary terms or that help to manage society in a mere technical way to follow the ideas of the government only, the social and behavioral sciences will loose one of their most important functions, namely the critical reflection on society. It is a future task for all researchers to solve the ostensible paradox of combining independence from governmental and economic organizations with an increased engagement with/openness toward policy-relevant issues or the policy relevance of their research.

As social scientists, we should however be aware that 'scientific expertise' as well as the increasing claims to it are no 'overwhelming force' (Stehr, 1992: 136), but are socially constructed and therefore can also be influenced by society.

Policy Networks

William D Coleman, University of Waterloo, Waterloo, ON, Canada

Abstract

The concept of a policy network first emerged in the 1980s and early 1990s as a means to study changing forms of public policy making, particularly the shift from vertical to more horizontal decision-making in states. In many instances, this horizontal approach to policy making was, in turn, a response to the growing internationalization of public policy. In recent years, more and more policy making is taking place 'beyond the state,' with the growing importance of global governance. Consequently, global policy networks have become increasingly important political participants.

Introduction

The concept of a policy network first emerged in the 1980s and early 1990s as a means to study the changing forms of public policy making, particularly the shift from vertical to more horizontal decision making in states. As horizontal decision making became more institutionalized in the governments of many countries, important changes in governance were taking place beyond nation-states at regional and global scales. Intensifying globalization processes were leading to the institutionalization of more decision-making at these supranational scales. The concept of 'global governance' emerged in the late 1980s, pointing to these new global policy-making fora. The policy-making processes for areas of global governance involved newer, more complex forms of policy networks and policy making. The analysis of various forms of policy networks begins with an analysis of policy networks involving nation-states and is followed by a discussion of the more complex networks of networks that have emerged as part of global governance.

A policy network refers to a set of informal and formal interactions between a variety of usually collective public (state and international governmental organizations) and private actors, who have different but interdependent interests. Operating in a more or less institutionalized setting, these actors are engaged in horizontal, relatively nonhierarchical discussions and negotiations to define policy alternatives, formulate policies, or implement them. Policy networks vary along two core dimensions: the structural pattern according to which public power is shared among the members and the degree and patterns of integration among the members. These two dimensions developed along distinct conceptual routes, only merging into a unified concept for the study of nation-state policy making in the mid-1990s. These two dimensions are analyzed empirically using a variety of methodologies including quantitative network analysis, elite interviews, and close examination of documents and archival materials. The principal challenges for the future of the analysis of policy networks include the resolution of their theoretical status and adjustment to global governance.

The Changing Context of Nation-State Policy Making

The state-focused definition of policy networks introduced above, came as a response to changes in the form of political decision-making in many democratic states. In particular, the standard notion of a clear separation between state and society, with the state being seen as the highest center for social and political control gradually came into question. As Mayntz (1993) observed, social modernization brought more importance to formal organizations in all areas of society, and with their strengthened position came an increasing fragmentation of power. Policy networks represented one intellectual conceptualization for responding to the escalating functional differentiation of social subsystems. With the state no longer being the sole entity capable of organizing society, there emerged a dispersion of expertise and competence among private and public actors; a multiplication of channels for mediation and agreement; and the inclusion of different levels of decision-making from the local to the supranational (Jouve, 1995). Consequently, nation-state public policies became much less likely to be produced by a unitary state with full control over all the resources necessary for implementing decisions in the public interest. Rather, nation-state public policy came to result from strategic interaction among several or many policy actors, each with a particular understanding of the problem and its own individual or institutional self-interest (Scharpf, 1997; **Table 1**).

Table 1 Forms of public policy beyond the nation-state

	International public policy	*Transnational public policy*	*Global public policy*
Key actors	States	States, nongovernmental organizations, corporations, social movements, individuals	States, nongovernmental organizations, corporations, social movements, individuals
Scale of activity	Intraregional Interregional Global	Intraregional Interregional	Global

The Historical Development of the Concept

The sharing of political power between public and private actors became the first avenue of enquiry that led to the development of the policy network concept. In the mid-1970s, Schmitter and Lehmbruch (1977) suggested that the concept of corporatism be reconsidered as a conceptual tool for understanding the particular relationships between public and private actors. They pointed to these relationships emerging in the management of macroeconomic policy in several European democracies. The revitalization of the corporatism concept coincided with other new concepts suggested for capturing the changing patterns of power sharing between private and public actors: 'corporate pluralism' in Scandinavia, 'issue networks' in the United States (Heclo, 1978), 'policy communities' in the UK (Richardson and Jordan, 1979), and 'policy networks' (Katzenstein, 1978).

The early focus in this research was on broad, macro-characteristics of nation-state political systems. As these concepts became more familiar, however, a number of scholars noted their potential relevance for understanding private–public relations in more specialized sectoral policy arenas. Drawing on a growing number of empirical studies, these scholars began to develop typologies of different structural patterns of public–private interaction at the sectoral or meso-level (Atkinson and Coleman, 1989; van Waarden, 1992), prompting a certain spate of definitional disputes. By the mid-1990s, however, sectoral and state corporatism, pressure pluralism, clientelism, issue networks, and state-directed networks generally were accepted as core structural types at the nation-state level.

In addition to patterns of power sharing between public and private actors, a second line of inquiry developed, focusing on the degree of integration among the various actors involved in these horizontal policy-making settings. Rhodes (1990) and Rhodes and Marsh (1995) targeted the degree of integration as their key variable and outlined a typology of the different types of 'policy networks' that ranged from fairly tightly integrated 'policy communities' to very loose and open 'issue networks.' The horizontal arrangements in policy making also triggered the interest of political sociologists interested in patterns of communication between large organizations. Laumann and Knoke (1987) sought to identify network structures by examining how information was transmitted between policy actors, the nature of the resource transactions between actors, and the relative openness of boundaries in various policy domains. These studies employed quantitative social network analysis developed in sociology. By the mid-1990s, this quantitative approach had incorporated insights from other policy network writings (Pappi and Henning, 1998).

When speaking of the degree of integration of the policy network, it is usual to employ a concept that refers to the aggregate of actors involved. The term 'policy community' is utilized most commonly for these purposes, but terms like 'policy domain' or 'policy subsystem' are also employed. Research has established a number of factors that are related to integration:

1. Openness of the policy community. The more open the deliberations in the policy community tend to be, the less integrated they are likely to become.
2. Size of the policy community. The larger the number of members of the policy community, the greater the obstacles to high integration.
3. Frequency of interactions among community members and the degree to which these interactions become 'institutionalized' (as opposed to remaining ad hoc and fluid). Institutionalization normally enhances the degree of integration.
4. Membership stability. The more changeable the membership of a policy community, the less integrated it will be.
5. Density and structure of information exchange. The denser the ties for information exchange and the more direct the relationships, the more integrated the policy community.

Another, particularly important factor affecting the level of integration of a policy community is the degree to which its members share basic beliefs, values, and norms. Some actors within a given policy community may come to share a set of deep normative core beliefs and from these develop basic strategies and policy positions (Sabatier and Jenkins-Smith, 1993). These 'advocacy coalitions' create 'spaces of meaning' within the policy community that provide a framework for political action. The degree of integration of the policy community will be affected by how many distinct 'spaces of meaning' it holds. Sabatier and Jenkins-Smith suggest that policy communities will normally contain two to four advocacy coalitions. They add that the number will probably be higher when the policy community is newly formed and may dwindle to one dominant coalition as policy making becomes routine. The concept of an epistemic community developed in international relations has certain properties in common with Sabatier and Jenkins-Smith's 'advocacy coalition'. All or part of an epistemic community may act as an advocacy coalition. When this development occurs, these epistemic communities often provide important links between policy communities, whether in other nation–states or at the transnational level.

Different types of policy networks may be distinguished depending on whether state actors share political power with private actors and on the relative resource balance between private and public players. State actors may share political power by inviting private actors to participate directly in the formulation or implementation of policy. Here private actors become 'policy participants.' Corporatist and clientelist networks have this feature; or state actors may monopolize policy formulation and policy implementation, while listening to, or receiving submissions from private actors. In such a relationship, private actors perform as 'policy advocates.' Pressure pluralism is the most common network with this feature, but it also occurs in issue networks and state-directed networks. The decision by state actors to share political power affects the overall balance of resources between public and private actors in the policy network. Resources may be relatively balanced, they may favor the state actors, or they may advantage civil society actors. Both pressure pluralist and sectoral corporatist networks feature a balanced relationship. Private actors have the stronger position in clientelist and issue networks while public actors dominate in state-directed and state-corporatist networks.

The Theoretical Status of the Concept at the Nation-State Level

Although definitional disputes surrounding the concept have gradually been resolved, the overall theoretical status of policy networks remains subject to debate. Two fairly fundamental criticisms have been directed at the concept. First, Dowding (1995) has charged that the concept is nothing more than a metaphor and will thus fail to produce theories of the policy process. Secondly, the concept is said to have limited relevance because of an apparent lack of suitability for explaining policy innovations and policy change.

Policy Networks as Metaphors Only

Dowding has argued that the attempts to provide a middle range theory of policy making utilizing the policy network concept are bound to fail. He suggests that the driving forces of the explanation – the independent variables – are not characteristics of the network as such, but of the components within the networks. Variables such as the relative openness of a policy network are cast merely as reworked descriptions of policy phenomena. Related criticisms argue that policy network studies have failed to explain both the mutual dependence of public and private actors and the conditions under which particular policy networks arise (Thatcher, 1998). Critics also lament the lack of specificity of the hypotheses that do exist, a failing bound to render any empirical testing rather unconvincing.

Although useful for spurring discussion and reflection, there are several reasons why these criticisms may be premature. First, the criticisms undervalue the descriptive utility of the policy network concept. One of the most difficult empirical problems faced in the analysis of public policies is the specific determination of the actors of consequence in any policy domain. Although one might be able to begin to specify these actors by utilizing a good understanding of the formal institutions and the persons occupying key positions, such a specification is almost inevitably bound to be incomplete. Policy making is replete with informal relationships and the operation of subtle, somewhat opaque norms that empower certain actors in unexpected ways. Accordingly, the methodologies developed for delimiting a policy network have a broader use in policy analysis. By identifying the central actors in policy making, the analysis of the processes becomes more straightforward for determining the policy ideas that are translated into particular policy proposals through interchanges between identified sets of actors. This identification process becomes particularly helpful in the policy areas featuring polycentric governance discussed below.

Secondly, numerous empirical studies subsequent to the publication of Dowding's critique have provided convincing evidence of relationships between variations in policy networks and policy outcomes (**Table 2**). For example, Josselin's (1997) study of the negotiation of core directives for a single market in financial services in the EU, evaluates the extent to which different types of networks facilitate or hinder the promotion of the interests of member states in EU-level negotiation settings. She shows that a relatively closed corporatist network at the national level is a decided asset in promoting a unified position at the EU level. Conversely, however, a more fluid issue network makes such unity more difficult, while providing additional degrees of freedom in the fluid decision-making arenas that exist at the supranational level. Similarly, Daugbjerg (1998) relates the relatively closed character of corporatist networks to patterns of political change. The more closed and cohesive the network, the more incremental the pattern of change and the more stable the utilization of policy instruments. Coleman's (1996) study of the impact of globalization on the regulation of financial services at the domestic level traces relationships between particular types of policy networks and the varying adaptation of countries to these globalizing pressures.

Table 2 Variation in governance arrangements beyond the state

Level of institutionalization of international, transnational, global governing arrangements	*Levels of public sector activism in governing arrangements*	
	High	*Low*
High	Polycentric governance	Self-regulatory and private regimes
Low	Intergovernmental negotiations	Loose couplings

Finally, Dowding's critique is addressed by some scholars who are using more formal models. Pappi and Henning (1998) elaborated a complex model that suggests direct relationships between types of networks (pluralism, corporatism, clientelism, state-directed) and policy outcomes. Scharpf's (1997) 'actor-centered institutionalism' introduces network-based negotiation settings as one of several core types of forums for policy making. Drawing on game theory, he sets out a series of propositions that provide a basis for modeling negotiations between actors in such networks and deriving probable differences in policy outputs based on general welfare and distributive justice criteria. Both of these more formal theoretical approaches hold considerable promise for the development of a middle-level theory where policy networks will be an important independent variable.

Policy Networks and Policy Change

Policy networks have been conceptualized primarily using structural variables. Such structural characteristics are helpful for building descriptions of the policy process at a particular point in time and, more recently, for positing testable explanations of variations in policy outcomes. Dowding (1995) questions, however, whether these same variables are sufficient for explaining how and why policies change and why networks themselves change. Two avenues of investigation have been pursued for addressing these criticisms. The first focuses on the relationship between policy ideas and policy networks and the second draws on an analysis of boundary rules.

Sabatier and Jenkins-Smith (1993) argue that policy networks include one or more advocacy coalitions that are composed of actors who share deep-core beliefs, near-core policy beliefs, and secondary beliefs about the use of policy instruments. Changes in the relative dominance of advocacy

coalitions in a policy network may prompt policy change. Or members of coalitions may negotiate adjustment of secondary beliefs that, in turn, open the door to policy change. Paralleling Sabatier and Jenkins-Smith's work, Jobert (1995) argues that a 'political forum' and a 'scientific or expert' forum exist alongside a policy network. When politicians begin to experience problems that cannot be addressed well within a policy network, they begin to reach to these other fora for advice. To the extent that this advice is acted upon, the policy network may be dissolved, with new arrangements taking its place.

What both these theoretical arguments stress is the importance of looking at the interaction between policy ideas and the entities who share these ideas within a given policy network. Coleman et al. (1996) follow up on these insights by arguing that the degree of sharing of policy ideas in a given policy network will determine the approach to policy negotiations among the actors in the network. They hypothesize that the more that ideas are shared, the more policy discussions will take on aspects of what Scharpf (1997) has called 'positive coordination' or a 'problem-solving' decision making style. They suggest that positive coordination is more likely in closed networks, like corporatism, than in more open networks such as pressure pluralism. By coupling policy network structures to policy ideas, they then trace different patterns for how policy change occurs. Scharpf's work stresses the importance of looking at actor preferences and cognitive orientations in studying policy processes. The richness of his theoretical work offers further opportunities for improving theories of policy change.

The second avenue for improving explanations of policy change focuses on different types of boundaries within policy communities. Rhodes and Marsh (1995) note that a policy community can have several policy networks. These, in turn, may operate at two levels: a central level whose members dispose of considerable resources; and a peripheral level composed of those with few or no resources. Changes in the actors at the center of a policy community and thus in the dominant policy network, or movements from the peripheral networks to the dominant one, will be crucial intervening variables in explanations of policy change. Similarly, new actors may build peripheral networks over time and then contest the exclusivity of the existing dominant policy network. To the extent that new actors enter an existing policy network, they may bring about change in its structure. For example, entry of new actors into a previously closed corporatist network may foster sufficient dissent that the state refuses to involve private actors any longer in policy making. Once such actors are excluded, the network takes on pressure-pluralist characteristics, altering, in turn, the policy process and perhaps policy outcomes (Coleman et al., 1996).

Global Governance and Policy Networks

The growing policy making taking place beyond the state raises new challenges for policy network analysis because it has been used primarily to study nation-states and domestic policy making alone. In these changed circumstances, states remain important institutions in policy making but they are joined by other institutions creating situations of what Scholte (2005) has termed 'polycentric governance' as opposed to 'state governance.' Although scholars developed the concept of 'policy networks' to help in the study of policy making by nation-states, the concept retains its value in the analysis of global governance. In fact, the structural form of the network is dominant when it comes to policy making on a global scale.

Defining Global Governance

For the purposes of this discussion, I follow Scholte and define 'global governance' as: "a complex of rules and regulatory institutions that apply to transplanetary jurisdictions and constituencies" (2011: 8). In using the word transplanetary, Scholte is speaking of linkages between persons or organizations "situated at any inhabitable points on the earth" (2005: 59). The linkages are not confined to a particular country or to a region. They have the potential to be from anywhere to anywhere in the world. The definition also leaves open the possibility that global governance involves not only nation-states, but also other types of actors including business firms, civil society organizations, local governments, and regional groups and agencies (2005: 9).

Connected to the concept of global governance is the development of what might be termed a 'global public space' where policy making takes place. John Ruggie (2004: 219) refers to an emerging 'global public domain,' which he defines as: "an institutionalized arena of discourse, contestation, and action organized around the production of global public goods. It is constituted by interactions among nonstate actors as well as states. It permits the direct expression and pursuit of a variety of human interests, not merely those mediated (filtered, interpreted, promoted) by states. It 'exists' in transnational non-territorial spatial formations and is anchored in norms and expectations as well as institutional networks and circuits within, across, and beyond states." Similarly, Castells (2008) refers to a 'global public sphere' that exists with a political/institutional space that is not subject to any particular sovereign power. Rather it is shaped by relationships between states and global nonstate actors. He adds that "a variety of social interests express themselves in this international arena: multinational business, world religions, cultural creators, public intellectuals, and self-defined global cosmopolitans (2008: 80)." For both Ruggie and Castells, global governance takes place in these spaces when various constellations of the actors involved propose, debate, and agree upon policies and rules that are then implemented by both public and private actors including states.

Global Networks and Global Policy

The functioning of governance in these global spaces involves complex and variable networks. Scholars such as Ulrich Beck (2005), Manuel Castells (2008, 2009), and Phil Cerny (2010) argue that states, transnational corporations, civil society actors, and social movements transform themselves into collective actors in these global public spheres through the formation of networks. States form 'public' networks with one another for various functions, as Slaughter (2004) has observed. These might include sharing information,

coordinating policy, cooperating on enforcement, and exchanging particular regulatory forms (2004: 40). Castells (2008, 2009) argues that the "emerging network state" shares sovereignty and responsibility with other states and differing levels of government. There is also "flexibility of governance procedures and greater diversity of times and spaces in the relationship between governments and citizens compared to the preceding nation-state" (2009: 40). Other scholars such as Scholte see states as becoming less central to policy making. He speaks of the movement from "statism" to "polycentrism." Scholte argues that "governance has become distinctly multi-layered and trans-scalar. Regulation occurs at – and through interconnection among – municipal, provincial national macro-regional and global sites. No single level reigns over the others. Governance tends to be diffuse, emerging from multiple scales at once" (2005: 186).

As these examples indicate, globalization has brought on a need for global public policy, one of the functions of global governance. Global public policy refers to policies that are directed to the whole of the global polity, however disorganized and difficult the definition of its borders might be (Coleman, 2012). As Cerny (2010: 98) observes, "the constitution of the public itself is being transformed in the context of political (as well as economic and social) globalizing trends." For these reasons, 'global' public policy potentially draws input, advice and participants in its 'formulation' from anywhere in the world; the formulation of policies is potentially transplanetary. Similarly, once it is agreed upon, the given policy has the potential to be implemented in any place on the planet or in all places in the planet. This understanding does not mean that those involved in policy formulation come from everywhere in the world; rather it speaks to the potential that they could do so. Similarly, the definition leaves open the question of whether a given global policy is implemented in all places in the world; rather, it implies that no place in the world is necessarily excluded from receiving the benefits or complying with the requirements, of the policy.

The increased complexity of policy making on a global scale, in turn, leads to different structures for global policy networks. Generally speaking, these networks take the form of 'networks of networks.' Castells identifies two mechanisms that come into play in these circumstances. First, there is the "ability to constitute network(s)" and the capacity to "program/reprogram the networks" in pursuit of policy goals of the given networks (2009: 45). Secondly, there is the "ability to connect and ensure the cooperation of different networks by sharing common goals and combining resources" (2009: 45). Therefore, in this global policy context, the hypothesis is that the most effective global policy networks will be those which "possess the most transnationally interconnected resources, power and influence" (Cerny, 2010: 106). Cerny adds that successful builders of these networks of networks are those who are "able to build cross-border networks, coalitions and power bases among a range of potential allies and adversaries" (2010: 106), and are "able to coordinate and organize their strategic action on a range of international, transnational and translocal scales" (2010: 106).

The complexity, instability, and size of global policy networks pose significant challenges for their study. The structure and range of activities of these networks can vary widely from one policy area, like intellectual property rights or agricultural production, to others focused on global health or environmental degradation. Scholars approaching their studies from an international relations perspective have sought to conceptualize these networks by building on the notion of an international regime. Although an individual international regime (composed of states) might be relatively tightly organized, they are often not able to respond fully to global policy issues. In response to this limitation, Keohane and Victor note the emergence of 'regime complexes' as responses to global governance challenges. "Regime complexes are marked by connections between the specific and relatively narrow regimes but the absence of an overall architecture or hierarchy that structures the whole set . . ." (2011: 8). In such a scenario, the regime complexes participate to varying degrees in policy processes involving different levels of cooperation. In essence, they operate as networks of more narrowly defined regimes that have a particular common interest in a set of policy issues. What is distinctive about these particular networks is that the states remain the dominant, if not the only, players in the pursuit of global policy goals.

Other scholars argue that maintaining the centrality of states in studying global networking, underplays other structural forms where networks of states share authority with networks built with different types of institutions. Biermann et al. (2009) suggest that the kind of state centrism in the regime-complexes hypothesis can be avoided by working with the concept of "global governance architectures." They define such architectures as: "the overarching system of public and private institutions that are valid or active in a given issue area of world politics." This system comprises organizations, regimes, and other forms of principles, norms, regulations, and decision-making procedures. Architecture can thus be described as the "meta-level of governance" (2009: 15). Biermann et al. develop the architecture further by noting that these can vary in their degree of fragmentation. At one end, the 'governance architecture' can be 'synergestic,' that is, built around a 'core institution'; in contrast, the architecture defined as "conflictive" is comprised of "different, largely unrelated institutions" (2009: 19). In this latter ideal type, the degree of coordination among participating global policy networks will be low. Between these two ideal types, Biermann et al. define a third architecture titled "cooperative" where participating institutions and networks are loosely integrated (2009: 19–20).

Future Challenges

The concept of a policy network was designed in the first instance for the analysis of policy making at the national and more local levels. However, as globalization has increased the internationalization of many policy areas, the likelihood rises that several policy networks will be interacting with one another across different levels of decision-making. Future research, therefore, will need to focus on improving understanding of the relationships between policy networks at varying scales beyond the nation-state. Some of these networks will have the additional property of being transnational or global in character; that is, they will include

actors from nation-states and other actors operating at national, regional, and global scales.

The concept of policy community mediators offers one avenue for research on the relationships between policy networks (Coleman and Perl, 1999). In many of the more globally extensive policy domains, boundary rules will create overlapping memberships between policy networks, with mediators emerging from among those actors with joint memberships. Mediation can take place at two levels. First, a mediator may operate as a pragmatic policy broker who looks for opportunities to lessen conflict within and between policy networks in order to move the policy process forward. Secondly, and perhaps even more importantly, mediation takes place on an intellectual plane, involving the 'translation' of policy ideas and policy paradigms between policy networks. Mediators construct a new view of the world that has a place for the policy concerns of multiple networks and provides a language and set of norms that enable them to speak to one another. Research on linkages between policy networks and on the role of policy mediators will be crucial to further theorizing on policy networks in this globalizing era.

Policy Process: Nonprofit Institutions in the United States

Donald T Critchlow, Arizona State University, Phoenix, AZ, USA

Abstract

This article examines the development of expertise and policy knowledge from the late nineteenth century through today within the context of a strong antistatist tradition. The growth on nonprofit institutions, especially think tanks, emerged in the early twentieth century to bring nonpartisan expertise to public policy and government administration. In the post-World War II period, policy expertise became increasingly politicized but continues to play an essential role in public policy within the American system.

Modern governments requires specialized knowledge and administrative expertise. In the USA, government bureaucracies rely heavily on private research organizations and nonprofit foundations, operating outside of government, to provide this expertise. The expanded role of the federal government in the post-World War II era strengthened the network of relations among public agencies and private groups including nonpartisan research institutes. The peculiar relationship reflects a strong antistatist tradition in America, evident in the role of private reform organizations in the early and late nineteenth century. In the late twentieth century, nonpartisan research organizations such as the Brookings Institution, the American Enterprise Institute, the Heritage Foundation, and the Institute for Policy Studies gained prominence for providing specialized knowledge to government policymakers, even while these organizations reflected ideological positions in their research orientations.

The complexity of advanced industrial systems requires governments to acquire an enormous range of specialized knowledge and administrative expertise with which to order their affairs. Uniformity in demand, however, has not produced uniformity in the character and supply of knowledge for government purposes. There are significant variations, related to diverse cultural traditions in the means of acquiring knowledge and applying methods of expertise. For example, central government bureaucracies in Western Europe and Japan directly provide many more sources and opportunities for the development of policy expertise than they do in the USA, which in modern times has relied heavily on private research organizations operating outside government bureaucracies for functional expertise. As the federal role in economic and social policy expanded in the post-World War II era, increased federal funding did not produce a commensurate increase in the size of government. Instead, it strengthened the complicated network of relationships among the federal government, state and local governments, and private groups, including nonpartisan research institutes (Alchon, 1985; Critchlow, 1985; Ricci, 1993; Smith, 1991).

In this policy system, the federal government operates indirectly, through intermediary organizations in state and local government, and in civil society (Heclo, 1980). This reliance on private, nonpartisan research organizations imparts a unique quality to the acquisition and use of knowledge by the administrative state in modern America.

The vast size, complexity, and expense of this system of acquiring knowledge by government in the USA suggests the pluralistic nature of the American polity, deeply rooted in its republican distrust of centralized government. This distrust of centralized government found expression in the nation's constitution, drafted in Philadelphia in 1787. Its famous beginning 'We the people' asserted that the source of its authority rested in the people rather than state or centralized government. This distrust of \centralized government found expression in the antistatist Jeffersonian–Jacksonian tradition that emerged early in the nation's history.

Social Investigation in the Nineteenth Century

In the environment of relatively weak centralized government prior to the US Civil War, the craft of social investigation developed within a middle-class subculture of reformers, many of them women, who documented the plight of slaves, the poor, prisoners, and the insane. The affinity of antebellum social reform and feminism became evident in reports issued by American abolitionists who documented the conditions of slave life, as well in reports on the care of prisoners, the indigent, and the insane. In the 1840s, social reformer Dorothea Dix issued a series of groundbreaking reports to state legislatures calling for the humane care of the mentally ill. This tradition of empirical research into social problems conducted by private individuals associated with reform movements was extended late into the nineteenth century (Marshall, 1937; Nelson, 1992; Leach, 1989; Daniels, 1968; Dupree, 1957).

By the outbreak of the Civil War, state legislatures in the most populous states regularly received detailed narrative and statistical reports on dependency, crime, public health, labor conditions, and economic development. These reports relied more on democratic and humanitarian sentiments associated with moral reform than they did on claims of science and disinterested expertise. Female reformers, as suggested by the role of Dorthea Dix, played an especially important role in this early endeavor to bring social knowledge to state legislatures and the public (Furner and Lacey, 1993; Ross, 1991).

While the capacity for social knowledge grew on the state level, the role of the federal government's activities in the pursuit of knowledge remained limited generally to surveying, land exploration, and modest technological development

through private contracts. This relative institutional impoverishment reflected a unique antistatist tradition in America, reinforced by sectionalist politics of the period. The major institution in Washington for the gathering and accumulation of scientific and social knowledge remained the Smithsonian Institution, which opened in 1846 at the instigation of the individual for whom it was named. In the decades following the Civil War, the Smithsonian Institution became a center for people such as Francis Walker, John Eaton, John Wesley Powell, and Carroll D. Wright, who took leading roles in establishing a rudimentary infrastructure of social investigation in the nation's capital. These individuals served as conduits for a transition from moral reform to scientific reform.

The Twentieth Century

By the beginning of the twentieth century a large resident class of scientific and professional civil servants had emerged in Washington. In 1904, the US Bureau of Census reported that 3919 civil servants fell into the classification of 'professional, technical, and scientific' workers. Within this group, nearly 1100 people were described as 'special agents, experts, and commissioners,' while another 300 or so were designated simply as 'scientific experts and investigators' (Lacey, 1993: pp. 127–170, Ross, 1991; Blumer et al., 1991; Keller, 1977; Skowronek, 1982; Wilson, 1909).

Many of the early organizers in the Smithsonian Institution played a critical role in the establishment of the American Social Science Association (ASSA) in 1865. The ASSA sought to serve as a clearinghouse of social knowledge in order to promote reform in education, public health jurisprudence, finance, and social economy. Directly influenced by the achievements of the Sanitary Commission during the Civil War and modeled on the British National Association for the Promotion of Social Science, the ASSA attracted commercial elite groups interested in promoting sound fiscal and monetary policy; lawyers, doctors, ministers, and teachers who sought professional affirmation; and middle-class reformers who combined humanitarian moral reform with the new scientific spirit. In this way, the ASSA, and other professional organizations that arose during this period, paved the way for a new liberalism, grounded in social empiricism (Haskell, 1977; Furner, 1975, 1993).

These reformers called for new measures of efficiency and economy in voluntary charity organizations and in public administration. Behind this concern with efficiency and economy lay a deep conviction that the polity was threatened by corruption of partisan political machines serving special economic interests. These political machines, run by local and state political bosses, consistently manipulated the mass of voters to maintain political power in flagrant disregard of any notion of public morality or efficiency and economy in government. Thus progressive reformers called for new social knowledge to help restore political order and representative government to American society. Beneath the catchphrase 'efficiency and economy' – the rallying cry of reformers – lay strong antimajoritarian values fused with antiparty perspectives (Critchlow, 1985; Alchon, 1985; Karl, 1974).

This movement for efficiency found early expression in late nineteenth-century charity endeavors. Amid concern that relief was being wasted on the undeserving poor, new professionals were brought into charity organization to centralize recipient roles, provide vouchers for relief funds to be distributed to recipients, institute periodic checks on recipients, and implement budget systems within agencies to keep a close watch on funds. Essential to this reform was the use of data gathering through statistical measures and new accounting procedures. Behind this movement lay a sentiment expressed by industrialist Andrew Carnegie, who declared, "One of the most serious obstacles to the improvement of our race is indiscriminate charity." Carnegie's infatuation with the new social sciences would lead him to create a number of new nonprofit philanthropic institutions concerned with the gathering of public knowledge (Lagemann, 1989).

At the vanguard of this movement for efficiency and economy in government were university trained and highly specialized social scientists. In the latter half of the nineteenth century, the basis of social science research was transformed from deductive reasoning derived from natural law into inductive procedure founded on historical analysis and empirical research. This new methodology allowed social scientists to mask any preoccupation with political matters in the terminology of scholarly objectivity and empirical research. The transformation of political impulses into the quest for public knowledge and administrative solutions reflected the aspirations of a new professional class anxious to gain influence in a highly industrialized society through expertise. They sought reform by placing 'the best people' – objective-minded experts – in the government (Ross, 1991; Haskell, 1977).

The call for efficiency and economy in government, and the need to develop new public agencies for the gathering of public knowledge essential to restoration of representative government, began on the municipal level first in New York with the creation of a Bureau of Municipal Research in 1905, organized by social scientists and civic-minded philanthropists and businessmen. Municipal research bureaus would be established in several other US cities. Central to these municipal research bureaus was the creation of executive budget systems that allowed a strong executive office, public officials, and the general electorate to track how public funds were spent. Essential to the functioning of an executive budget was the creation of an agency staffed by nonpartisan experts who would prepare and analyze budgetary finances and expenditures (Critchlow, 1985; Karl, 1974; Smith, 1991).

This demand for an executive budget system reached the national level under the administration of William H. Taft in 1910. When Taft assumed office in 1909, the federal budget stood at over a billion dollars and the federal debt had reached disturbing proportions, largely as an aftermath of the 'Panic of 1907.' In these circumstances, Taft was able to persuade Congress to appropriate $100 000 for a commission on efficiency and economy in government. To staff the commission, Taft called on the best social scientists in the country. After 2 years of painstaking work, the Taft Commission came out with its report, *The Need for a National Budget*. Yet, because the proposal was made in an election year, a recalcitrant Congress refused to enact an executive budget system. The failure of the Taft Commission did not dismay reformers, however. In 1915 they created the Institute for Government Research – the predecessor to the Brookings Institution. Only in 1921 during

the Harding administration would budget reform be enacted in the Budget and Accounting Act of 1921.

Taft's successor, Woodrow Wilson reflected in many respects the deep ambivalence that middle-class Americans felt about the state during the early twentieth century. An array of new government agencies was now involved in conservation, consumer protection, corporate regulation, trade practices, and monetary and financial policies. Yet Wilson, in his pioneering essay on public administration warned that the model of Prussian administration should be avoided in America. He declared that European bureaucratic practices would have to be adapted to fit the highly decentralized form of government in the USA. If the European model is to be employed in the USA, he told his fellow reformers, "We must Americanize it … We must learn our constitutions by heart and we must get the bureaucratic fever out of its veins" (quoted in Cuff, 1993: p. 390).

Until America's entry into the war in April 1917, neither the federal government's defense department nor civilian departments had considered mobilization tasks. As a consequence, private planning proceeded public planning. Financial and manufacturing firms such as J.P. Morgan and Du Pont Corporation, by receiving Allied war orders, were among the first to assess the financial, technical, and labor requirements of munitions production (Brownlee, 1993).

War, however, forced the enormous administrative expansion of the federal government in the short period between April 1917 and November 1919. New government agencies appeared in haphazard fashion, drawing corporate and academic personnel into government management. This involvement led many to the belief that the capacity for public knowledge and for effective social action rested in the mobilization of private, public-spirited professional and business groups willing to work in cooperation with a sympathetic state. The war demonstrated for these individuals how to forge a uniquely American combination of state–society relations.

Herbert Hoover sought to put this insight into practice as Secretary of Commerce in the Harding and Coolidge administrations, and later as president, by using the techniques of private–public cooperation he had learned as a wartime administrator. Hoover sought to develop state–voluntary cooperation in the collection of specialized data required for rational decision making in both the private and public sectors. For Hoover and others concerned with public knowledge, the war revealed just how essential government knowledge was for economic and social planning. Through the development of an administrative state he sought to develop new mechanisms for collecting public knowledge without the coercive element of state power (Hawley, 1974).

In keeping with his views about the credibility of privately financed researchers, Hoover arranged for the Rockefeller Foundation, founded in 1913, to fund a comprehensive survey of social changes in American life between 1900 and 1930. The 3-year study resulted in the massive 1600-page *Recent Social Trends in the United States: Report of the President's Research Committee of Social Trends* (1933). This study presented the full panoply of available knowledge for public purposes (Karl, 1974; Hawley, 1974; Alchon, 1985).

Although state capacity for gathering public knowledge expanded dramatically during the Great Depression era, World War II, and the postwar period, the federal government continued to rely indirectly on intermediary organizations in state and local government, and in civil society, for the accumulation of knowledge. The commensurate increase in the size of the federal government led to the creation of fluid networks of policy specialists, who operated in and between government and the private sector, identifying policy issues, generating 'solutions' to policy problems, and overseeing and evaluating the implementation and administration of policies within their specific areas of competence (Heclo, 1980).

Role of the Think Tanks

Essential to these policy networks are private policy research institutes or 'think tanks,' a peculiarly American social invention. By the 1990s there were an estimated 1200 nongovernment think tanks of various descriptions. World War II and the postwar continuation of a large defense program, as well as expansion of federal social programs, was a watershed in the evolution of the American think tanks.

At the end of World War II, Americans made a political decision to have government train, subsidize, and regularly consult a sizable population of civilian experts on such issues as defense, welfare, health, and economic stability. Of the major think tanks, only the Brookings Institution (1916) and the Carnegie Endowment for International Peace (1910) were founded before World War II. The American Enterprise Institute was founded during the war in 1943 (Critchlow, 1985; Smith, 1991; Lagemann, 1989; Dickson, 1971).

Although think tanks are ostensibly nonpartisan, in many instances they function as extensions of state power, their influence rising and falling with changes in governments and shifts in the ideological climate of the country. In other cases, think tanks function more independently, questioning and monitoring state strategies and structures. For example, the Rand Corporation of the 1940s and 1950s was designed to strengthen the programs of the US Air Force, whereas the Institute for Policy Studies has been a major center of criticism of US foreign policy, domestic social programs, and policies in the areas of civil rights and poverty.

Often the ideological orientation of these think tanks reflected changes in the historical context and political climate, as indicated by the dominant trends in high and popular culture, changes in voting behavior, and shifts in political leadership (Ricci, 1993).

The course of the Brookings Institution from the New Deal through the end of the twentieth century reflected these ideological currents. While Brookings studies in the early 1930s criticized New Deal programs, the Brookings Institution under its president Harold Moulton tried to avoid becoming directly involved in partisan politics. By 1937, however, the institution had emerged as a vociferous critic of New Deal fiscal policy.

In response to the new postwar environment and the reluctance of foundations to fund an institution they perceived as ineffective or out of touch, Robert Calkins, former head of the General Education Fund at the Rockefeller Foundation, agreed to head the institution. Calkins reorganized Brookings and recruited social scientists with liberal credentials and government experience. This new group had close ties with

government, and unlike the devotees of the earlier nonpartisan ideal, aligned themselves closely with presidential administrations. In 1965, when Calkins retired, Brookings was representative of mainstream Keynesian economic thinking, and its growing influence was reflected in renewed foundation support, especially from the Ford Foundation. Under Calkins' successor, Kermit Gordon, Brookings' reputation as a liberal democratic think tank was well entrenched. As a result, the institution became a major research center and a holding area for policy experts who were temporarily out of office. In these years, the Brookings Institution became a major center for policy innovation in welfare, health care, education, housing, and taxation policy (Critchlow, 1985; Smith, 1991).

Divisions over foreign and domestic policy opened cracks in the liberal consensus in the early 1970s, however, leading many observers to see the institution as isolated from large segments of business. In 1976, the board of trustees appointed Bruce MacLaury to head the institution. A former regional Federal Reserve banker and treasury official, MacLaury successfully courted business support, increased corporate representation on the board of trustees, and moved the institution toward a more moderate ideological stance.

By the 1970s, the Brookings Institution confronted competition from other major policy research institutions, especially the American Enterprise Institute and the Heritage Foundation – both viewed as conservative research institutions close to the Republican Party.

The American Enterprise Institute (AEI), which was founded in 1943 as the American Enterprise Association (AEA), illustrates the experience of a conservatively oriented research institution that expressed deep ambivalence about the post-World War II policy consensus (Critchlow, 1985; Smith, 1991). The key figure behind the establishment of the AEA was Lewis Brown, chairman of Johns-Manville Corporation. Brown realized that the New Deal had changed the political environment for business and, although he expressed anxiety about the level of government intervention, he accepted much of the New Deal program. From the start, the AEA reflected a conservative bias.

In 1954, A.D. Marshall, head of General Electric, assumed the institution's presidency and immediately hired William Baroody S. and W. Glenn Campbell, both staff economists at the US Chamber of Commerce, to head the research program. Under their guidance, AEA was gradually built into a modern research institute under its new name, the AEI. Principal support came from private foundations and major corporate sponsors. The institution's reputation was enhanced when the Nixon administration called upon a number of AEI associates to fill government positions. The AEI also emerged as a successful proponent of economic deregulation.

In 1977 Baroody retired and his son, William Baroody Jr., took over the presidency of the institution. To improve its standing in the academic community, the AEI assembled an impressive staff including Melvin Laird, William Simon, Robert Bork, Michael Novak, and Herbert Stein. The tenure of William Baroody Jr., however, ended abruptly in the summer of 1987, when an increasingly restive board of trustees forced his resignation because of cost overruns and declining revenues. Moreover, despite the large number of AEI staffers who held appointments in the Reagan administration (30 left AEI to join the administration in its first 2 years alone), members of the New Right, suspicious of what they considered the centrist orientation of the institution, voiced bitter criticism of the AEI.

Baroody's successor, Christopher DeMuth, bolstered the conservative orientation of the institute by bringing on board several former Reagan administration officials with strong rightist reputations.

The founding of the Heritage Foundation in 1973 revealed a new ideological climate in the analysis of public knowledge (Edwards, 1997; Peschek, 1987). Founded by Edwin Feulner and Paul Weyrich to provide rapid and succinct legislative analysis on issues pending before Congress, the Heritage Foundation sought to promote conservative values and demonstrate the need for a free market and a strong defense. The Heritage Foundation's articulation of conservative values in social policy, education, and government activities placed it at the forefront of New Right activity. Although sympathetic to the Reagan wing of the Republican Party, Heritage's commitment to conservative economic theories and social values allowed the institution to be critical of both republicans and democrats. The Heritage Foundation remained relatively small in its early years, but the election of Ronald Reagan to the presidency in 1980 enhanced the institution's prestige. By the mid-1980s the Heritage Foundation had established a solid place in the Washington world of think tanks as a well-organized, efficient, and well-financed research organization that called for the turning over of many government tasks to private enterprise, a strong defense, and a cautious approach to Russia and China.

During these years, myriad other think tanks emerged in Washington representing a range of ideological positions and specialized policy interests, including the left-oriented Institute for Policy Studies (1963) and the libertarian-oriented CATO Institute (1977). Think tanks concerned with national security included the Center for Strategic and International Studies (1962) and the Center for National Security Studies (1962) affiliated with the American Civil Liberties Union (Friedman, 1983).

These private institutions served to supplement social research conducted by federal agencies and institutions. By the 1990s the number of personal and committee staff of Congress exceeded 11 000, with a further 20 000 people responding to the information needs of the legislature from the Congressional Budget Office, the Office of Technological Assessment, and the General Accounting Office (Lacey, 1993). The executive branch commands far greater numbers. By the 1990s the scale of spending by the federal government for the acquisition and application of public knowledge was massive. Funding is currently routed through an estimated 180 bureaus and agencies. This research includes a mixture of 'in-house' research conducted by career civil servants, and a larger body of research conducted by outside parties via grants and contracts on a 'for-profit' basis and some of it by university based scholars on a 'not-for-profit' basis. An estimated one-third of this research activity is supported by the federal government to meet its needs, while the remaining two-thirds is authorized for state and local government, school systems, policy forces, welfare agencies, and industrial and agricultural groups. In addition, a vast array of trade and professional organizations and 'public interest' groups conduct research in the areas of environmental policy, consumer affairs, civil rights, and foreign policy issues (Critchlow, 1985). While the government relied on think tanks

for policy innovation, program review, and policy assessment, the federal government relied on nonprofit service providers to implement social programs. In this way, the expansion of the welfare state in the 1960s and 1970s created a seeming paradox that remains apparent in the contemporary regime: the rapid growth of the nonprofit, voluntaristic sector occurred at the same time that federal social policy became increasingly centralized and active. The parallel development of the centralized welfare state and the voluntary sector was no coincidence. The growth of federal social programs mobilized the nonprofit sector, while in turn the nonprofit sector, through policy innovation and program implementation, helped legitimize the modern welfare state.

Thus, as the traditional federal system that had existed since the founding of the nation eroded in the 1960s, when the federal government extended its powers at the expense of state power, the nonprofit sector was called upon to help design, implement, and administer social programs that had once been within the jurisdiction of the public sector (Hall, 1992; Kameran and Kahn, 1989; Salamon, 1992). As a consequence, the nonprofit sector expanded in the 1960s at the very time that the federal government enlarged its powers over the states. The result produced an unusual phenomenon – government centralization produced greater nonprofit sector voluntarism (Critchlow, 1999).

The 'Mixed' Welfare State

Between 1965 and 1980 the American social welfare state underwent a significant transformation, with government spending on social welfare increasing by 263% in inflation-adjusted dollars (Gilbert, 1983; Critchlow, 1999). The expansion of the welfare state promoted the emergence of a government–nonprofit partnership. Increasingly in the 1960s, the federal government generated the funds but then turned over the delivery of services to other public state and local organizations, and private nonprofit organizations. The private, nonprofit sector became a major beneficiary of this system of services. By the 1980s, the federal government alone provided $40 billion in support to the private nonprofit sector, while state and local governments provided additional amounts from their own resources (Salamon, 1992).

Federal demand enabled the nonprofit sector to grow by leaps and bounds. In 1940 there were only 12 500 charitable, tax exempt organizations. By 1990, there were over 700 000, with most of this growth taking place after the 1960s (Salamon, 1992; Hall, 1992; Critchlow, 1999). While the federal government centralized social policy through congressional mandates, administrative and legislative regulations, and new funding arrangements, the delivery and implementation of these programs were placed in the hands of state and local governments and nonprofit organizations.

The growth of philanthropic foundations in the twentieth century, especially in more recent years has contributed significantly to role of the increase in policy knowledge. Increasingly philanthropic foundations such as the Rockefeller Foundation, the Ford Foundation, and the Gates Foundation operate in an increasingly complex environment reflecting the diversification of the federal government's role in public policy. For example, the Low Income Housing Tax Credit Act of 1986 has encouraged public funds to match grants from the Ford Foundation through the Local Initiatives Support Corporation and Enterprise Community Partners. In supporting these activities, Ford Foundation urban policy experts have undertaken studies and work on local community low-income housing problems. Similarly, the nonprofit Trust for Public Land has worked with private individuals and for-profit corporations to preserve land. The Davide and Lucile Packard Foundation spent over a $100 million since 1998 for the Conservating California Landscape Initiative to present 343 000 acres. The rapid growth of community foundations have been used to support expert studies and policy initiatives in the areas of conservation, tax policy, economic development, education at all levels, and cultural and arts projects. The well-funded Gates Foundation, for example, is extensively involved in social and health policy studies and projects in the United States and the world. While nonprofit foundations after 9/11 experienced strict regulation to ensure that funds were not being directed to groups supporting terrorism, nonprofits have accelerated their contributions to the increase in policy knowledge.

The emergence of the 'second welfare state' in the last three decades of the twentieth century – contrary to the concerns of those who feared that government would replace the nonprofit sector altogether – created a vibrant nonprofit sector. Government, in turn, came to rely on this sector to design and implement programs, undertake demonstration projects, contract with other private agencies, and provide outside consultation and independent review agencies and activities.

As this second welfare state emerged, the nonprofit sector was called upon to fulfill a number of distinct functions. Nonprofit organizations served as *funding intermediaries* distributing funds to other parts of the nonprofit sector, *service-providing organizations* involved in health care, education, counseling, adoption assistance, and *political action agencies* supporting particular pieces of legislation or candidates for political office (Salamon, 1992). By providing public services, these nonprofit organizations developed a symbiotic relationship with the federal government. By 1990, government grants, contracts, and reimbursements accounted for 31% of nonprofit service organizations' income. Just 18% of the total income that nonprofit organizations receive comes from private giving (Salamon, 1992; Hall, 1992).

The proliferation of government and nonprofit institutions involved in public policy marshals expert against expert, testing the credibility of each and enriching the information environment in which policy discourse occurs and decisions are taken. Indeed, on highly technical issues, opposing experts often directly contradict one another. Yet the growth of public and private agencies involved in collecting public knowledge allows for a more democratized policy process – much closer, in a sense, to the Jeffersonian–Jackson vision of an open, competitive democracy.

Still, two qualifications are in order: neither Jefferson nor Jackson envisioned a world of competing experts representing various interests and ideological positions; and secondly, this contemporary world of competing institutional research is not equally open to all comers. Access to financing is one limitation, and access to those in power is another.

The proliferation of expertise and the expansion of government knowledge that has arisen in response to the demand for

more policy inquiry have not necessarily improved the information base on which political decisions are made. The emergence of more complicated patterns of political mobilization by a larger and more diverse array of interests and groups has necessarily politicized the nature of policy knowledge and thereby redefined the nonpartisan ideal espoused at the beginning of the twentieth century. Competition for attention to research places heavy demands on the time and attention of legislators and policy-makers who, in a value-laden universe, are left, ultimately, to decide what information counts for them on the basis of their own values. A widespread acceptance of relativism, embodied institutionally in public and private research organizations, has irrevocably altered the process of social investigation and the uses of social knowledge.

Politeness and Language

Abstract

This article assesses the advantages and limitations of three different approaches to the analysis of politeness in language: politeness as social rules, politeness as adherence to an expanded set of Gricean Maxims, and politeness as strategic attention to 'face.' It argues that only the last can account for the observable commonalities in polite expressions across diverse languages and cultures, and positions the analysis of politeness as strategic attention to face in the modern context of attention to the evolutionary origins and nature of human cooperation.

What Is Politeness?

If, as many have claimed, language is the trait that most radically distinguishes *Homo sapiens* from other species, politeness is the feature of language use that most clearly reveals the nature of human sociality as expressed in speech. Politeness is essentially a matter of taking into account the feelings of others as to how they should be interactionally treated, including behaving in a manner that demonstrates appropriate concern for interactors' social status and their social relationship. Politeness – in this broad sense of speech oriented to an interactor's public persona or 'face' – is ubiquitous in language use. Since, on the whole, taking account of people's feelings means saying and doing things in a less straightforward or more elaborate manner than when one is not taking such feelings into consideration, ways of being polite provide probably the most pervasive source of indirectness, reasons for not saying exactly what one means, in how people frame their communicative intentions in formulating their utterances.

There are two quite different kinds of feelings to be attended to, and therefore there are two distinct kinds of politeness. One kind arises whenever what is about to be said may be unwelcome, prompting expressions of respect, restraint, avoidance ('negative politeness'). Another arises from the fact that long-term relationships with people can be important in taking their feelings into account, prompting expressions of social closeness, caring, and approval ('positive politeness'). There are many folk notions for these kinds of attention to feelings – including courtesy, tact, deference, demeanor, sensibility, poise, discernment, rapport, mannerliness, urbanity, as well as for the contrasting behavior – rudeness, gaucheness, social gaffes, and for their consequences – embarrassment, humiliation. Such terms label culture-specific notions invested with social importance, and attest both to the pervasiveness of notions of politeness and to their cultural framing.

How Can We Account for Politeness?

Since politeness is crucial to the construction and maintenance of social relationships, politeness in communication goes to the very heart of social life and interaction; indeed it is probably a precondition for human cooperation in general. Politeness phenomena have therefore commanded interest from theorists in a wide range of social sciences. Three main classes of theoretical approach to the analysis of politeness in language can be distinguished.

1. *Politeness as social rules*. To the layman, politeness is a concept designating 'proper' social conduct, rules for speech and behavior stemming generally from high-status individuals or groups. In literate societies such rules are often formulated in etiquette books. These 'emic' (culture-specific) notions range from polite formulae like *please* and *thank you*, the forms of greetings and farewells, etc., to more elaborate routines for table manners, deportment in public, or the protocol for formal events. Politeness is conventionally attached to certain linguistic forms and formulaic expressions, which may be very different in different languages and cultures. This is how the 'person on the street' tends to think about politeness, as inhering in particular forms of words.

Some analytical approaches to politeness are formulated in terms of the same sorts of culture-specific rules for doing what is socially acceptable, for example, the work by Ide and others on Japanese politeness as social indexing or 'discernment' (see Watts et al., 1992). In these approaches, politeness is a matter of social norms, and inheres in particular linguistic forms when used appropriately as markers of pre-given social categories. This approach is most appropriate for fixed aspects of language use – the more or less obligatory social marking of relatively unalterable social categories.

2. *Politeness as adherence to Politeness Maxims*. An alternative approach takes the position that the linguistic forms of politeness are not a matter of arbitrary convention but are motivated by general principles. During the 1970s this perspective was formulated in linguistic pragmatics in Gricean terms, with politeness seen as a set of social conventions coordinate with Grice's Cooperative Principle for maximally efficient information transmission ('Make your contribution such as required by the purposes of the conversation at the moment'), with its four 'Maxims' of Quality, Quantity, Relevance, and Manner (*see* Pragmatics, Linguistic). Lakoff (1973) suggested that three 'rules of rapport' underlie the choice of linguistic expression, rules which can account for how speakers deviate from directly expressing meanings. Choice among these three pragmatic rules ('Don't impose,' 'Give options,' 'Be friendly') gives rise to distinct communicative styles. Leech's more detailed

 http://dx.doi.org/10.1016/B978-0-08-097086-8.53072-4

proposal (1983) is in the same vein. Complementary to Grice's Cooperative Principle, Leech postulates a Politeness Principle – 'Minimize the expression of impolite beliefs,' with the six Maxims of Tact, Generosity, Approbation, Modesty, Agreement, and Sympathy. As with Grice's Maxims, deviations from what is expected give rise to inferences. Cross-cultural differences derive from the different importance attached to particular maxims.

The conversational maxim approach shares with the social norm approach the emphasis on codified social rules for minimizing friction between interactors, and the view that deviations from expected levels or forms of politeness carry a message.

3. *Politeness as face management*. A more sociological perspective places 'face work' at the core of politeness. Goffman (1967) considered politeness as an aspect of interpersonal ritual, central to public order. He defined face as an individual's publicly manifest self-esteem, and proposed that social members have two kinds of face requirements: positive face, or the want for approval from others, and negative face, or the want not to offend others. Attention to these face requirements is a matter of orientation to Goffman's "diplomatic fiction of the virtual offense, or worst possible reading" (Goffman, 1971: 138ff), the working assumption that face is always potentially at risk, so that any interactional act with a social–relational dimension is inherently face-threatening and needs to be modified by appropriate forms of politeness.

Universal Principles of Politeness

Brown and Levinson (1987, henceforth B&L) introduced a new perspective by drawing attention to the detailed parallels in the construction of polite utterances across widely differing languages and cultures, and arguing that universal principles underlie the construction of polite utterances. The parallels they noted are of two sorts: how polite utterances are linguistically constructed, and how the polite expression of utterances is modified in relation to social characteristics of the interlocutors and the situation. At least three social factors are involved in deciding how to be polite: (1) one tends to be more polite to social superiors; (2) one tends to be more polite to people one doesn't know. In the first case, politeness tends to go one way upwards (the superior is less polite to an inferior); in the second, politeness tends to be symmetrically exchanged. In addition, (3) in any culture there are norms and values affecting the degree of imposition or unwelcomeness of an utterance, and one tends to be more polite for more serious impositions. In language there are also detailed parallels, with the linguistic structures for realizing particular kinds of politeness showing remarkable similarities across unrelated languages. The politeness of solidarity is characterized, for example, by use of intensifiers, in-group identity markers and address forms, exaggerated intonation patterns, and forms for emphasizing agreement and avoiding disagreement. Avoidance-based politeness is characterized by forms expressing self-effacement, formality, restraint, deference, with the use of honorifics, hedges, indirect speech acts, and impersonalizing mechanisms like pluralization of pronouns, nominalization, and passive. All of these involve elaborating the expression of communicative intent in specific ways that deviate from direct Gricean communication.

Why then are these kinds of detailed parallels across languages and cultures to be found in the minutiae of linguistic expression in socially analogous contexts? Explanations in terms of arbitrary social norms or rules can account for politeness in a particular social group, but not for the cross-cultural patterns, which seem to require a strategic account in terms of what people generally are trying to do when they are being polite. B&L proposed that such deviations from Gricean efficient communication are motivated by the universal human assumption that interactors have 'face,' in the form of desires for the interactional acknowledgment of their social persona. Following Goffman, they posited two kinds of face: positive face desires for affirmation and social closeness, and negative face desires for separation, personal territory, and freedom from unexpectable impositions. These give rise to two styles of politeness – one addressed to ratifying the personality of the interlocutor (positive or solidarity politeness), and the other designed to mitigate or minimize impositions (negative or respect politeness).

B&L (1987) proposed an abstract model of politeness wherein human actors are endowed with two essential attributes: *face* and *rationality*. Face consists of two specific kinds of wants: positive face (i.e., the desire to be approved of, admired, liked, validated), and negative face (the desire to be unimposed upon, unimpeded in one's actions). The second ingredient in the model – rationality – provides for the ability to reason from communicative goals to linguistic means that would achieve these goals. From these two assumptions – face and rationality – and the assumption that speakers mutually know that all speakers have these two attributes, B&L developed a model of how speakers construct – and interpret – polite utterances in different contexts on the basis of assessments of three social factors: the relative power (P) of speaker and addressee, their social distance (D), and the intrinsic ranking (R) of the face-threateningness of an imposition. P, D, and R are seen as abstract social dimensions indexing kinds of social relationship (P and D) and cultural values and definitions of impositions or threats to face (R).

B&L (1987) argued that the actions people do when talking with one another – for example, requesting, informing, offering, complaining – have implications for each others' face, and they identified a wide array of speech act types that have the potential to threaten face: 'face-threatening acts' or FTAs. They distinguished five general types of strategies of politeness, ranging from avoiding an FTA altogether, to carrying it out but 'off record' (indirectly). On-record realization of an FTA can be done without any redressive action at all ('baldly'). It may be carried out with positive redress, which is essentially approach based, addressing the hearer's positive face wants by emphasizing closeness and solidarity. Politeness may also be carried out with negative redress, which is essentially avoidance based, addressing negative face wants for distance, deference, and freedom from impositions. Speakers are assumed to choose the linguistic framing of their utterance from this set of strategic possibilities according to the weightiness of the FTA, which is assessed with reference to the three contextually dependent social factors P, D, and R. For low levels of FTA threat, bald-on-record or positive politeness is most

appropriate and cost effective; for higher levels, negative politeness is required; for the highest threats, indirectness is the safe option.

The claim, then, is that, however culturally variable the kinds of social relationship and kinds of face threat might be, underlying them are human attributes (face, means-ends reasoning abilities) and pan-cultural social dimensions (relative power, social distance, ranking of face-threateningness) which universally go into the reckoning and the interpretation of strategic language choice, and hence one can derive the cross-cultural similarities in choice of linguistic realizations of politeness strategies that empirically seem to be in evidence. B&L (1987) claimed further that this model of politeness universals could be applied in particular cultural settings as an ethnographic tool for analyzing the quality of social relationships. Stable social relationships are characterized in part by stable patterns of language use, which may distinguish particular societies or social groups. Analyzing these stable patterns (for example, the distribution of T/V pronoun usage across individuals and social groups) can reveal important aspects of social relationships and their changes over time.

Critiques of the B&L Politeness Model

The goal of B&L to formulate a cross-culturally applicable 'etic' set of concepts in terms of which politeness can be analyzed in 'emic' terms for any particular society was ambitious. Etic analytical concepts are drawn from a universal set, defined from outside a particular cultural perspective and used to compare behavioral or linguistic systems across different cultural groups, in contrast to emic ones which are meaningful within a specific culture and are used to describe a system in its own terms. Critics of the B&L model reveal several major points of contention about whether it is legitimate at all to generalize across cultural systems and, if so, how a theory of politeness should be formulated.

The Universality of Face

Many critics have challenged B&L's formulation (via Goffman and Radcliffe-Brown) of positive and negative face wants as a valid way of conceptualizing the universal underpinnings of politeness. Negative face, in particular, considered as wants for freedom from imposition, appears entirely too embedded in Western individualism to sit well with conceptions of face in some other (e.g., east Asian) cultures. In part, this is due to a misconstrual: in the B&L model, face wants are abstract, they do not necessarily correspond clearly to conscious emic notions. What B&L (1987) claimed is that *underlying* diverse folk notions is a core of two interactionally relevant wants (for ratification, and freedom from imposition) which seem to be cross-culturally applicable, as desires concerning one's public self-image in the context of the moment which are *assumptions oriented to in interaction*. Other theorists (e.g., O'Driscoll, 1996; Arundale, 1999) have argued for notions of positive/negative face that are even more abstract, in terms of merging/individuation or closeness/separation, as the universal heart of politeness.

Challenges to the universality of the model also extend to the proposed hierarchy of increasing politeness (from bald-on-record to positive to negative to indirectness). Assessments of the P, D, and R factors are situationally and culturally very variable; it is possible to accumulate different strategies in one utterance and to balance elements of negative politeness with positive politeness in one act, and indirectness is not always seen as the most polite option. These observations have led some researchers to argue against the possibility of identifying any kind of universal basis for polite behavior; politeness is simply incommensurate across societies. Those who take this extreme relativistic line can have no explanation for the observable cross-cultural parallels in patterns of language use, for how people manage (sometimes) to understand others from culturally different backgrounds, or for cross-linguistic parallels in the diachronic sources of honorifics from politeness strategies.

Politeness as Communicated or Taken for Granted

In contrast with rule-based approaches, B&L (1987) insist that politeness inheres not in words or in sentences per se, but in utterances uttered in a context, by virtue of the successful communication of a polite attitude or intention. Polite utterances are not necessarily communicating 'real' feelings about anothers' social persona, but expressing contextually expected concern for face. This concern is an 'implicature,' an inference of polite intentions, not a feature inextricably attached to particular linguistic forms. Politeness is ascribed to a speech act, or to an interactional move (if you prefer), not to a strategy or its linguistic realization per se.

In other approaches (for example, Fraser's (1990) 'conversational contract,' Watts et al.'s (1992) 'politic behavior'), politeness is taken to be the expected *background* to interaction; it is normally not communicated but consists in following expectations as to appropriate behavior.

Broad versus Narrow Scopes for Politeness Theory

A narrower view takes politeness to be strategic orientation to potential face threats; there are some situations (e.g., task-oriented ones) where politeness may be subsumed to other goals, and there are many reasons for being indirect in speech other than politeness (e.g., humor, irony, rhetorical force). Many motivations other than politeness guide human behavior. A more inclusive view sees politeness as orientation to the social-relationship dimension of every interaction, with attention to face taken to be an omnipresent necessity. The whole continuum from extreme politeness through a quite neutral level of politeness (maintaining the status quo, 'discernment') to rudeness (outright intentional threat) then needs to be brought into the theory.

Politeness from the Point of View of the Individual, the Dyad, or the Social Group

The B&L model takes the interacting dyad as its unit; it is about how interlocutors make inferences of politeness from one another's deviations from Gricean efficient communication, and how stable patterns of strategies characterize dyadic interaction, providing an index to the quality of the social relationship. Many politeness strategies are quintessential examples of 'intersubjective perspective-taking' – putting yourself in the others' position. A major goal of B&L (1987) was to insist on the centrality of social interaction as a significant level of social life, intermediate between the individual and society, where social/cultural facts (status, role, values, norms, rights, and obligations) are integrated with individual ones (goals, plans, and strategies).

Yet the Gricean foundation of the theory and the speech-act-based formulation of the B&L strategies have made many see the model as purely psychological (how a speaker calculates how to frame an utterance). Arundale (1999), for example, argues instead for a theory of how face is *jointly constituted* in ongoing interaction. In fact, we need both perspectives: face is indisputably interactionally created, negotiated, and manipulated. Nevertheless, it can be considered from the point of view of the individual speaker or hearer (as B&L do in their production/comprehension model), or of the society or social group (as 'face constituting theory' and most sociolinguists do).

The Indeterminacy Problem

B&L (1987) proposed their model as a concrete discovery method for analyzing social relationships in any society by studying members' speaking practices. However, the usefulness of this model as an ethnographic tool is undermined by a number of complexities that arise when examining naturally occurring language usage data. The problems of mixing strategies in a single utterance and ordering of strategies across utterances are compounded by the indeterminacy of context-dependent P, D, and R assessments and by difficulties of establishing whether an utterance is intended to be taken as ironic, joking, or teasing. All of these make it hard to code levels of politeness in any concrete situation and to assess how different expressions interact to produce a composite message in an utterance. These are problems with any theory in terms of actors' intentions when applied to empirical data; as both interactors and conversation analysts know, it is not always possible to be certain what interlocutors' intentions are at a particular point in natural interaction. The B&L model of politeness as originally formulated clearly needs elaboration and revision.

New Directions in Research on Politeness

The intellectual climate of research has changed radically in the four decades since the B&L model was fostered at the University of California, Berkeley, in the early 1970s. Since then an enormous amount of research has addressed politeness from a variety of perspectives, in work coming from all the social sciences that have an interest in social interaction. Empirical studies of politeness have greatly increased the amount of information we have about social interactional styles in different contexts and different societies. Yet the research emphasis in work on politeness has been largely on cross-cultural differences in politeness, with little attention addressed to the cross-linguistic and cross-cultural parallels which motivated the theory. Indeed, very few studies provide the crucial kinds of evidence necessary to test the universality of any theory of politeness, namely, for a range of particular societies, an 'ethnography of speaking' providing evidence of naturally occurring language usage across a wide range of different contexts, showing how politeness is interactionally modulated in relation to local social factors in that society.

Researchers, impressed by different cultural views of face, propriety, conviviality, and the individual, have generally preferred to study culture-specific patterns of language use. Yet the significance of politeness lies far beyond the culture-specific rules of appropriate behavior and speech that seem so salient to members of the culture. This wider significance lies in the fact that by regular patterns of language choice humans interactively construct their social relationships. Research in this area therefore needs to be based in a theory of social interaction that takes into account both our common human nature and ability to communicate cross-culturally, and the cultural differences which can sometimes lead us to misunderstand one another. Despite its shortcomings, the B&L model retains its hold on research on politeness largely because it provides a coherent set of concepts for analytically dissecting polite speech in different societies and contexts. It is also the only theory that begins to provide an account for the detailed cross-cultural parallels in polite speech.

In the new millenium, research agendas and priorities have changed. The study of social interaction has turned to focus on the interactional foundations of language, its cognitive underpinnings, and its instantiation in the brain. Research continues on the sociocultural contexts of language use, with a major emphasis on face as co-constructed in interaction and on the sequential development of this interactional process, with impoliteness as well as politeness as the object of enquiry. A corresponding emphasis on the sequentially developing contexts for face and related politeness issues (preference structures, entitlement, 'ownership' of knowledge, 'fairness') appears in the field of Conversation Analysis, for example, in Pomerantz and Heritage (2013), Lerner (1996), Heinemann (2006), Curl and Drew (2008), Heritage and Raymond (2005), and Heritage (2013). There is also an increasing trend toward the comparative study of naturally occurring interaction from a conversation analytic perspective (Sidnell, 2009), as well as new theoretical approaches to the study of cultural models (e.g., Strauss, 2004) and of human social relations – for example, Agha's (2007) view of social relations as created through language use shaped by reflexive models of social life. All of these developments can be expected to feed into our understanding of politeness.

Another new direction is the emerging emphasis on the cooperative basis of human sociality and on the interactional underpinnings to language, its evolution, and its ethological base; Goody (1995), Enfield and Levinson (2006), Tomasello (2008, 2009), and Stivers et al. (2009) can be mentioned here. There are recent investigations into the cognitive and brain underpinnings to interaction (e.g., De Ruiter et al., 2010; Noordzij et al., 2009, 2010), work which forms a new context within which the search for universal bases for politeness can be pursued, exploring the cognitive prerequisites for politeness, such as recursive theory of mind, without which the elaborate demonstration of mutual regard would be impossible. This context suggests that the inhibition of aggression, the soothing character of politeness work, and the elaborate interpersonal ritual that politeness represents, may have played a crucial role in the evolution of the specifically human forms of social life and culture, and, indeed, may have been a fundamental factor driving the evolution of human cognition.

Conclusions

Politeness has attracted an enormous amount of research attention since the 1970s, and continues to be a major focus for research in disciplines concerned with social interaction.

The study of politeness phenomena can provide insight into widely differing issues; foci of interest correspondingly differ widely. They include, for example, analyses of the sequential development of politeness in natural interaction, the study of cross-cultural pragmatics and misunderstanding, the ethnography of speaking of face and politeness in different cultures and contexts, politeness strategies as providing the stylistic coherence of particular types of interaction (e.g., gender differences in speech style), politeness as a functional motivation for linguistic structure (e.g., honorifics), the social psychology of face management and interpersonal perception, applications of politeness theory to the analysis of formal ritual and to a view of culture as 'rhetoric,' or forms of effective expression.

Research on politeness has, however, been much weaker on the theoretical front. A major limitation is the kinds of data used in analyses. A large proportion of studies take as their data people's conscious evaluations of politeness expressed in sentences, judgments which tend to be both prescriptive and stereotypical. Far fewer studies use as data recordings of situated conversational exchanges to explore how politeness is achieved sequentially in naturally occurring discourse, and only a handful provide the crucial kind of evidence necessary to test the universality of any theory of politeness: for a particular society, an 'ethnography of speaking' providing evidence across different contexts to show how politeness is modulated in relation to social factors (P, D, R, and others) in that society.

The emphasis in research has been largely on cross-cultural *differences*, with insufficient attention addressed to the cross-linguistic/cross-cultural parallels which tend to be taken for granted when they are not disputed. But politeness has a significance far beyond the P's and Q's of appropriate behavior and speech. The wider significance of politeness is in the interactional, communicative, day-to-day basis of social life and the conduct of social relationships. Research on politeness needs to be anchored in a theory of social interaction that takes account *both* of our common human nature and our ability to communicate cross-culturally and of cultural differences which make us sometimes misunderstand one another.

Abstract

Campaign messages broadcast through radio, television, or the Internet, or circulated via handbills, newspaper advertisements, or word of mouth provide people with much of their political information. Research on the effects of such messages has had both a positive and normative component. The main strain of positive research concerns how information translates into electoral opinions and behavior. The main stream of normative research concerns whether people are adequately informed, or even misinformed, and how we can improve the information content of political advertising. This article briefly considers recent empirical research on both matters. The principle finding of empirical research in this area is that advertising mainly reinforces viewer's predispositions. As a result, advertising imparts considerable information to viewers, but appears to have modest effects on election outcomes.

Political advertising has been the subject of intense scholarly investigation for nearly a century. Two agendas underlie this strain of social science inquiry.

The first agenda seeks to measure how political advertising, and campaigns generally, produce votes. Candidates' campaign advertisements are a major source of information about electoral choices that voters face. The intellectual origins date to Gosnell's studies of voting in Chicago in the 1920s (Gosnell, 1927, 1935). How much and how do advertisements influence election outcomes? The answers to these questions have very practical uses for political practitioners, who seek information that can guide campaign strategies, and for social scientists, who seek to explain how elections are won. Many social scientists question whether political advertising has any influence on elections, because elections are readily forecasted using indicators of peace and prosperity. Key writes in *The Responsible Electorate* that "The hullabaloo of a presidential campaign so commands our attention that we ascribe to campaigns great power to sway the multitude. Campaigning does change votes and it does bestir people to vote. Yet other influences doubtless outweigh the campaign in the determination of the vote" (1966, p. 9). On election forecasts, see Rosenstone (1983).

The second agenda concerns the extent of voter autonomy. Are votes hollow echoes of campaign messages, or does political discourse enable voters to reach reasonable decisions that reflect their own preferences and values? Electoral reform motivates much research on advertising and voter autonomy. If political advertising easily misleads voters, then restrictions on campaign advertising or some sort of 'political consumer protection' may be necessary in order to make democracy work. To the extent that there is a scholarly consensus on this matter it is that concerns about voter autonomy are overdrawn. Behavioral research in a wide variety of settings indicates that advertising has modest but important effects on election outcomes: advertising can make a difference in a close election, but it does not appear to persuade large numbers of voters to turn against a candidate or party that is well-known, well-liked, and represents the voters' interests.

Advertising and Vote Production

Political advertising covers a wide range of media that candidates use to mobilize supporters to turn out or to persuade people to vote for them. Commentary on political advertising often equates it with television advertising, as, for instance, when European commentators descry the 'Americanization' of their politics. But even in the US there is, in fact, much less television in politics than is often supposed. Campaigns for the US House of Representatives, for instance, use as much direct mail as television advertising. And in local campaigns candidates use little television but a vast range of other media, including mail, billboards, lawn signs, telephones, and door-to-door canvassing (Key, 1966).

Campaigns' usage of different media appears to follow the same principles that apply to firms. Candidates choose what media to use based on the productivity of the media and their relative prices. Variation in the mix of media used at different levels of office suggests that there are economies of scale to different sorts of advertising. Personal contact is reputed to be the most effective mode of political communication and it is a staple of local elections everywhere. But it is impossible to spend 15 min with each of the millions voters in a national election.

Mass media are most cost-effective at reaching broad constituencies. Evidence of the rational use of media comes from US House races. The average household in the typical House district receives about two pieces of mail and sees at least two television advertisements. However, candidates choose a mix of advertising media based on the prices and productivity of those means of reaching potential voters (or consumers). Campaigns for the US House in districts with expensive broadcasting media (such as Los Angeles and New York) spend $2.50 on mail for every $1 broadcasting, or three pieces of mail and 15 s of advertising per person. House campaigns in districts with inexpensive broadcasting (such as Dayton, Ohio and El Paso, Texas) spend $10 on broadcasting for every $1 on mail, or one piece of mail and 8 min of advertising per person. (For details see Ansolabehere et al., 1999a.) To my knowledge, similar sorts of calculations have not been conducted for other countries, though it is evident

from patterns of media usage that parties and candidates in Europe, Australia, and elsewhere are similarly responsive to media prices. (See, for example, Blumler, 1983 and Australian Election Commission, 1997.)

Social science research has focused on how voters respond to the overall volume and different sorts of campaign advertising that they receive. The estimated effects depend in part on the methods used.

Three different approaches have been taken to the study of advertising. First, laboratory and field experiments have been used to gain precise measures of the effects of advertising exposure in specific campaign settings. Such studies control what messages individuals receive and then measure differences in opinions or behaviors in response to different sorts of messages (e.g., Gosnell, 1927, 1935; Ansolabehere and Iyengar, 1996; Gerber and Green, 1999; Norris 1999).

Second, studies of aggregate data correlate the observed vote to levels of campaign spending. Some of these studies design their inquiries around 'quasi-experiments' which exploit factors that change levels of spending (such as personal wealth) in order to measure the effect of spending on the vote. The seminal work in this vein, for both American and European researchers, is Jacobson (1978). Subsequent research has improved on this model; see, for example, Gerber (1998). Races involving three or more candidates pose statistical problems in estimation of vote production functions, for which widely accepted statistical models have not yet been developed. Third, surveys associate reported vote or political attitudes with reported or recalled exposure to messages. Almost all research outside of the US relies on survey methods. For a discussion of the problems with survey-based measures of campaign effects see Ansolabehere et al. (1999b). Analogous with the aggregate studies, instrumental variables can solve such problems.

Experiments, which offer high internal validity, show a remarkably consistent set of results about the capacity of advertising to produce votes. Researchers observe exactly what messages citizens see and can design the study so that other factors do not confound the effect of the experimental manipulation. Perhaps the earliest experimental study of political advertising and campaigning took place in the 1920s in the US. To measure the mobilizing effects of direct campaigning, Gosnell (1927) sent a cadre of graduate students out to canvass a set of blocs of the city of Chicago in an effort to manipulate the levels of voter contact. They found higher in turnout ranging from 4 to 7% in the areas that the students canvassed over the areas that they did not canvass. Fast forward to the 1990s. Gerber and Green (1999) replicated Gosnell's study in several towns in southern Connecticut. They found increases in participation similar to those reported in the Chicago studies 70 years earlier. They also found increases in vote shares of candidates in the neighborhood of 4 percentage points for two pieces of mail. In a series of laboratory experiments conducted in Los Angeles from 1990 to 1993, Ansolabehere and Iyengar (1996) found strikingly similar results for television advertising. Exposure to a 30-s television advertisement raised the percentage of viewers who intended to vote for a candidate by 4 to 10 points. These and many other experiments show substantial effects of political advertising on candidates vote shares. Those who see a broadcast message, receive a mailing, or talk to a campaign worker are between 4 and 10% more likely to support the candidate being promoted.

Aggregate studies of campaign spending yield similar, albeit lower estimates of the effectiveness of campaign advertising. Using fairly complicated, and controversial, statistical models, researchers have attempted to measure the marginal effect on the vote of spending an additional campaign dollar. Such techniques yield estimates ranging from miniscule effects of a dollar spend on the vote to estimates of approximately $10 per vote. The key papers in this subfield are Jacobson (1978), Green and Krasno (1988), and Gerber (1998).

Such estimates are in the right ballpark, but the wide range of estimates in the literature on campaign spending suggests that additional work finding valid statistical models is in order before we can put much confidence in the estimates emerging from this literature.

The problem is that it is difficult to sort out cause and effect in aggregate electoral data. Consider, for example, two similar legislators: one holds a highly competitive seat and the other holds a very safe seat. The legislator in the competitive seat must spend large amounts of money to win re-election; the legislator in the safe seat is unlikely to be challenged and if they are they do not need to spend much to retain the seat. In this example the correlation between spending and vote shares is negative! To fix this problem researchers have taken a 'quasi-experimental' approach, using factors such as candidate wealth, which affect directly how much candidates spend and in turn affect their vote shares. Improving such statistical models remains an important research challenge.

Survey research has presented the most modest estimates of the effectiveness of advertising. A long line of studies report minimal effects of campaigns in general and of advertising in particular on the vote (in the US, see Campbell et al., 1960; in the UK, see Norris, 1999). Serious problems of question validity lead to serious doubts about these research findings. In the laboratory setting, Ansolabehere and Iyengar (1996) document that survey-based measures of advertising exposure miss one exposure for every one that they detect. This degree of misreporting is sufficient to explain why surveys often produce insignificant findings or even estimates in the 'wrong' direction. Quasi-experimental techniques analogous to those used in aggregate studies can correct measurement problems (Bartels, 1993).

Beyond differences in media and methodologies, a further theme in the study of political advertising is the mechanism through which messages become votes. There are three. Advertising may solidify an uncertain vote (reinforcement), it may stimulate a supporter to vote (mobilization), and it may lead a voter to change their mind (conversion). This typology is due to Berelson et al. (1954). Although political observers often talk of 'swing' voters and movement in the polls, there appears to be relatively little evidence in experiments or surveys of conversion. Few Republicans decide to vote Democrat and few Democrats decide to vote Republican in response to political advertisements. Perhaps the strongest evidence against conversion, though, comes from nonpartisans. Nonpartisans, especially low information independents, are the least responsive to political advertising.

Reinforcement appears to be the dominant mechanism in political communication. For instance, in the experimental

research reinforcement produces the clearest effect on the vote. Nonpartisans and viewers of the opposite party as the sponsor of the ad showed no statistically significant response to a candidate's ads. Low information partisans of the same party as the sponsor showed by far the strongest favorable response to political advertising. That effect shrank, though it remained statistically and substantively large, with the partisan's level of information and interest in politics (Ansolabehere and Iyengar, 1996). This pattern suggests that political advertising fits neatly into the more general model of information acquisition developed by Zaller, in which both predisposition to believe a piece of information and prior levels of knowledge determine responsiveness to new information (Zaller, 1992).

Mobilization has proved the most controversial of the three mechanisms. Experimental research on political advertising has called into question the longstanding belief among political scientists that campaigns are inherently stimulating affairs. Berleson et al. (1954) describe the process in detail. This is essentially the model behind retrospective voting developed by Key (1966) and widely used to understand elections in the US, Europe, and elsewhere. A large number of experimental studies have demonstrated that not all viewers are stimulated to vote by political advertisements. For example, nonpartisan and low information viewers exposed to negative advertising appears express significantly lower intentions to vote than others. As a result, negative campaigning can produce lower turnout among the key group of 'swing' voters and an electorate that reflects two ideologically opposed groups.

The demobilizing effects of negative advertisements on nonpartisans underscores the difference between reinforcement and mobilization. Negative advertising might win the highest vote share, mainly by reinforcing partisans, but it can lead to lower overall participation.

One important caveat about the state of social science research on political advertising is in order. The bulk of the research on the effectiveness of political advertising has been conducted in the United States. Many of the findings about mobilization and reinforcement likely depend on the electoral system, which influences the number of parties or candidates. The dynamics of campaigns and the consequences of advertising appear to be quite different in races involving more than two candidates. Johnston et al. (1992) provide excellent examples of political communications having complicated effects on competition in Canada's multiparty system. Careful experimental research on multicandidate and multiparty races, though, is in its nascency.

Voter Autonomy

The central problem for democratic theory in modern societies is that people apparently know little about the choices they face and they have little incentive to seek new information. Candidates and parties, then, have very strong incentives to provide information to voters at little or no search costs: candidates try to reach us, rather than us, them. As a result we are highly reliant on what politicians choose to say in their advertisements.

This is the problem of voter autonomy. By one telling voters have abdicated to political elites the important jobs of choosing what issues will be discussed, what elections and therefore government will be about, and even what we will think as people walk into the voting booth. From this view, people are highly susceptible to false or deceptive advertising and will vote for the candidate whom we see the most rather than the one we think is best representative. Regulation of the volume and content of political advertising may, therefore, be necessary.

The counter argument is that voters, even though they do not know much by way of details, have a clear sense of what they themselves value or prefer, and, in order to win elections, politicians must adjust their messages to what the voters want. In crafting their advertisements, a candidate selects issues on which he or she can make electoral gains, because the voters care about it, because the candidate has a strong record, or because the candidate has have taken the more popular position. This leads to majoritarian biases in what is discussed, but that is the essence of elections.

Voter autonomy presents a much more difficult set of research questions. In order to say that people are or are not misled by political communications, we must establish what it is that they prefer or value a priori. The effects of advertisements must then be judged against that baseline. Two questions are central.

First, do advertisements lead people to choose a candidate who is less good for their interests or values? Research showing strong reinforcement and few conversion effects suggests that the answer to this question is probably no. In both survey and experimental data it appears that people who lean toward a party become more solidly in favor of that party as the campaigns progress (Ansolabehere and Iyengar, 1996, Chap. 4; Gelman and King, 1990). An important variation on this arises from tactical voting in Britain, Canada, and other countries. As campaigns progress, voters supporting a candidate or party in third place or lower might vote for the second place candidate if they prefer that candidate over the front-runner. This seems to have happened in the 2000 Mexican election as support for Cardenas fell over the course of the campaign and support for Fox, who was in second place most of the race, rose.

Nonpartisans tend to move very little, and tend not to vote. The immediate political implication is that campaign discourse is polarizing: it ultimately pits Democrats against Republicans, Conservatives against Labourites. The low amount of conversion suggests, however, that people fundamentally are not misled.

Second, can advertising set the public agenda, or are people mainly responsive to what they themselves care about? While agenda setting effects have been widely documented in other areas of study, they have received surprisingly little careful study in the field of political advertising. Early evidence of agenda setting is provided by Bereleson et al. (1954, Chap. 12). Two careful studies stand out. Jamieson's (1992) *Dirty Politics* documents how the Republican and Democratic strategists use their advertising and the news media to magnify their own agendas, especially Republican's usage of crime and race. Johnston et al. (1992) demonstrate that the debate over free trade completely transformed the Canadian voters' priorities, without changing their preferences on free trade itself.

Reinforcement and agenda setting can hold conflicting implications for voter autonomy. Partisan reinforcement

suggests that there is little evidence that people vote against their expressed preferences; agenda setting suggests that people are vulnerable to what the campaigns choose to discuss. There may, however, be no contradiction here. It may indeed be the case in each of the examples discussed that voters were simply very receptive to new agendas, and that elections gave voters an opportunity to change public policies on trade, affirmative action, and other issues from those set decades earlier.

New Directions

Political advertising poses both methodological and normative challenges for social scientists, and our understanding on both levels has advanced considerably over the last two decades. Advertising has important effects on election outcomes, but it does not appear to lead people to vote for candidates with whom they fundamentally disagree. It, therefore, does not on the whole undercut the normal workings of majority rule in democratic elections.

In terms of methods, a high priority for further inquiry is bridging the gaps between experimental, aggregate, and survey methods, and developing more powerful quasi-experimental approaches to correct measurement and simultaneity problems. To this end, research on vote production, which has relied mainly on quasi-experiments in aggregate data, should make greater use of experiments to map out features of the vote production function more fully, especially the effects of repeated exposures to messages and interactions between the messages and the viewers preferences.

In addition, there is considerable need for research on political advertising outside the US. The American focus of campaign research stems in part from existing regulations on elections and media. The US imposes few limits on how candidates and parties raise and spend campaign funds, on their access to media, and on what can be said on the various media. As a result, the US has proved a rich field to study advertising effects. Research on campaigning in European countries has placed a much greater emphasis on electoral laws, political parties, and tactical voting. There is, however, growing interest in campaign effects in European political science.

Beyond methodological differences, there is the matter of why. Reinforcement and mobilization are a sufficiently well-established phenomenon that it is worth opening up the black box. Why are these the routes through which political advertising works, and why not conversion? The highly inductive approach of empirical researchers is likely to pay the biggest dividends, as political theory has yet to produce a powerful model of why people vote.

Abstract

Anthropologists have approached the comparative study of politics in different ways, depending on their general theoretical perspectives. This article provides an overview of the history of political anthropology from around 1940 until now. The author first discusses different anthropological attempts to define politics, or the political, and looks at the classic, British structural-functionalist anthropology of politics in the 1940s and 1950s. The author thereafter examines a series of significant changes that the anthropology of politics has registered since the early 1970s and rounds off by discussing features of the last two or three decades' anthropology of the modern state, and by reflecting briefly on political anthropology's relationship to, and interest in, studies of forms of political violence. The article maintains that since the 1980s political anthropology has become less strictly disciplinary, and has gradually opened itself more to academic conversations with interests and views derived from political philosophy and political science.

Anthropology and the Definition of Politics

Political anthropology is a subfield of sociocultural anthropology, but like anthropology as a whole, it remains immune to precise delimitation. The core of political anthropology is the comparative, fieldwork-based examination of politics in a broad range of historical, social, and cultural settings. Today, it is common to see political anthropologists combine ethnographic work with history. Some analyze the symbolic forms and practices of a specific state bureaucracy, others a form of political activism, and yet others the perpetration of terror or torture, or the political effects associated with the everyday and ritual construction of a particular collective memory. The field of political anthropology has been, and continues to be, extensive, diverse, and shifting.

Anthropologists have defined politics in different ways, depending on their general theoretical–analytical interests and research questions. A typical anthropological point of departure today states that politics, or the political, must not be treated as a separate domain or field, but must be investigated as articulation between power relations, cultural processes, and historical trajectories. As one contemporary anthropologist, Steven Gregory, put it in his *Black Corona* (1998, p. 13), "For my purposes, politics refers to a diverse range of social practices through which people negotiate power relations. The practice of politics involves both the production and exercise of social relationships and the cultural construction of social meanings that support or undermine those relationships." The work that founded and gave shape to the classic, British structural-functionalist anthropology of politics in the 1940s and 1950s, *African Political Systems* edited by Meyer Fortes and Edward Evans-Pritchard, viewed a society's political organization as those structures or relations that maintain "social order within a territorial framework, by the organized exercise of coercive authority through the use, or the possibility of use, of physical force" (1940, p. xiv).

In the 1950s and 1960s, anthropologists gradually moved away from the more rigid structural-functionalist views, and many came under the influence of versions of action theory and interactionism. The reformulated political anthropology that emerged during these two decades saw politics in formal terms: political anthropology examines comparatively 'political behavior' – typically defined as (1) the search for power or influence and (2) a human constant, a universal aspect of societies.

In a remarkable study, *Society against the State* (1977 [1974]), the French anthropologist Pierre Clastres criticized all traditional political anthropology for having universalized a particular (Western) notion of political power, or politics, a notion that identifies political power with coercion or violence: "the kinship is closer than seems apparent between Nietzsche, Max Weber (state power as the monopoly of the legitimate use of violence), and contemporary" anthropology, he wrote (p. 4). What, Clastres asked, do we do with Amerindian societies in which "if there is something completely alien to an Indian, it is the idea of giving an order or having to obey" – in other words, societies where political life functions as a process 'beyond hierarchical subordination' and totally 'beyond coercion and violence' (p. 5). Are these societies not only without 'a state' but also without 'politics'? Or is there something wrong with a particular way of thinking about the nature of political power? Clastres replied that a genuinely cross-cultural political anthropology needs a wide and open definition of politics: "all societies, whether archaic or not, are political, even if the political is expressed in many voices, even if their meaning is not immediately decipherable; and even if one has to solve the riddle of a 'powerless' power" (p. 14).

One year before Clastres published his book, Talad Asad launched a pathbreaking critique of structural-functionalist anthropology, and of the mainstream anthropological project more generally, in *Anthropology and the Colonial Encounter* (1973). Asad's study and similar efforts helped partly to launch and partly to strengthen anthropologists' interest in colonial and postcolonial studies, and in history. Today, most in the discipline consider the issue of how to define politics in terms of a certain history: the notion of 'the political' appeared in Western Europe after the Reformation,

alongside the modern concepts of the state and democracy. The geographical and historical origin of the discourse of politics did not, however, preclude its being exported to the rest of the world. The anthropology of politics must therefore study varying, historically and culturally constituted definitions of the political – in brief, whatever the actors (leaders and masses, states and nongovernmental organizations) across the globe consider politics to be.

The use of the term 'political anthropology' was widespread in anthropology in the 1960s and early 1970s. Subsequently, it came to be used far less, indeed to be less fashionable, even among those in the discipline who evidently studied political phenomena. In 2002, an authoritative, instructive reader was published under the title *The Anthropology of Politics* (Vincent, 2002).

The Making of a Political Anthropology, *c.*1940–70

Before the publication of *African Political Systems*, structural-functionalist anthropologists had not formulated an explicit approach to the comparative study of politics. They had worked on 'religion' and 'kinship,' but not on 'politics.' That volume gave decisive direction to anthropological examinations of politics for at least two decades. Its authors' approach had five important features. First, to them the political question was primarily a matter of understanding how a certain 'order' was created and recreated in society, how particular institutions and mechanisms contributed to the maintenance of a sufficient measure of peace and cohesion in the social system. Second, although the structural-functionalists' general thinking about, and definition of, a political organization seemed premised upon universalization and naturalization of a specific, a European model, or a set of ideas about the nation-state, they did not study the state. Instead they followed Radcliffe-Brown, who in his Preface to *African Political Systems* suggested that instead of wasting time on the study of what he classified as a purely ideological construct, namely, 'the State,' it would be better simply to study forms of politics, forms of power and authority, and forms of government. The state, he wrote, is most often "… represented as being an entity over and above the human individuals who make a society, … and sometimes spoken of as having a will … or as issuing commands. The State in this sense does not exist in the phenomenal world; it is a fiction of the philosophers. What does exist is an organization, i.e., a collection of individual human beings connected by a complex system of relations …. There is no such thing as the power of the state" (1955 [1940], p. xxiii).

Third, these researchers were concerned to develop a taxonomic classification of types of political systems. They argued, for example, that Africa included three main types of society: those societies that had centralized authority, administrative machinery, clearly defined judicial institutions, and economic stratification; those societies that lacked centralized authority, administrative machinery, and judicial institutions – in brief, 'stateless' societies; and finally, those very small societies in which even the largest political unit embraced a group of people all united by kinship bonds, such as a roving extended family. Fourth, the structural-functionalists sought mainly to explain political systems in terms of synchronic examinations of mutual interdependence between institutions; generally they were little concerned with studying the past. And fifth, they demonstrated an impressive will, and ability, to show with rich ethnographic material why any productive anthropology of power and politics needs to remain intimately connected both with the anthropology of kinship and with the comparative study of religion. They generated a series of works documenting that the exercise of politics can be embedded, indeed apparently concealed, in the ordinary organization of kinship and marital bonds, and in forms of ritual life.

The best known example is Evans-Pritchard's (1940, 1955 [1940]) ethnographically based study of the 'stateless' political system of the Nuer, a pastoral people of southern Sudan. His analysis of the Nuer political order embodied the general views outlined above. The Nuer, Evans-Pritchard argued, were without chiefs or leaders with coercive or absolute authority over others, and he described their political systems as 'ordered anarchy' based on the principle of 'segmentary opposition.' Society's members were organized into clans and lineages based on male lines of descent from founding figures. Local groups constituted 'segments' of larger, more inclusive kinship units defined in terms of descent. This hierarchy of nested lineage segments of differing scale, Evans-Pritchard claimed, was derived from crucial moral-political values maintained by the Nuer. Obligations to back and help others in fighting were articulated in terms of kinship. Groups that were opposed at one level of segmentation, that of minor lineages, for instance, had a duty to unite in a conflict between the higher segmentary unit to which they all belonged and another unit of the same hierarchical level, such as a major lineage. These dynamics of 'fission and fusion' also ensured that Nuer society was able to act as a collective unity in conflicts with other 'tribes.' Evans-Pritchard's ahistorical, structuralist narrative of the Nuer quickly became enormously influential and was generalized into models of 'acephalous (primitive) political systems' and 'segmentary lineage theory.'

The reformulated political anthropology that gradually emerged in the 1950s and 1960s remained essentially based on synchronic investigations, and little preoccupied with the state. In addition, it continued to produce detailed ethnographies of connections between the practice of politics on the one hand and, on the other, the organization and uses of kinship and rituals. But in some ways, this so-called processual approach to the anthropological study of politics deviated from the earlier structural-functionalist school.

A major contribution on the road to the changed approach was Edmund Leach's *Political Systems of Highland Burma* (1954), which argued in favor of, and demonstrated, a more dynamic, more process-oriented type of examination. This study, which sought a way to treat and explain forms of social and political change, rested upon a simple, basic assumption: that a conscious or unconscious wish to gain power is an extremely common, probably universal human motive – and that persons faced with a choice of action will typically choose what helps to obtain power and recognition. Two important voices when the processual approach was given shape in the 1960s were the Norwegian Fredrik Barth (who wrote his doctoral work with Leach as supervisor) and the Englishman Fredrick G. Bailey. Both, like Leach, conducted research outside Africa, in Asia, and in the Middle East. Although it would be wrong to

consider the process approach as a coherent paradigm or theory, the transformed focus may be summed up under three headings.

First, the general interest in producing and discussing classification of types of political systems disappeared; already in Barth's first major work, *Political Leadership among Swat Pathans* (1959), this interest was entirely absent. Second, the new political anthropology shifted the focus of analysis away from those structures that secure order to the many activities and forms of action everywhere that express competition for influence, control, and leadership – in brief, forms of power struggle. Process analysis was based on the idea that political behavior and political processes ought to be studied in terms of networks of individuals and groups that employ power to achieve particular results. The objective became finding a way to model features of such competition and struggle for power. And third, new terms were put to use to study politics cross-culturally: terms like 'process,' 'strategy,' 'tactic,' 'maximizing,' 'political faction,' and 'political arena.' Most of these concepts have since been used by anthropologists, albeit to varying extents.

Culture, Power, and History

During the late 1960s and 1970s, the discipline registered rapidly growing interest in forms of Marxist-inspired perspectives, world-systems theory, and history. Anthropology developed a stronger awareness of the need to understand the historical process of Western global domination. Since the late 1960s and early 1970s, the discipline has also seen the emergence of symbolic anthropology, or the construction of a strikingly strong concern with the study of meaning. From the second half of the 1970s, the ideas of Foucault, Bourdieu, and Gramsci exercised considerable influence on anthropologists studying the relationship between power and meaning, including political forms and practices. As already noted, the category or label 'political anthropology' soon became old-fashioned. Yet anthropologists still continued to examine political phenomena. In the period from the early 1970s to the late 1990s, anthropologists studying political practices and processes were preoccupied with at least three wide, overlapping problem areas: 'power and culture,' 'domination and resistance,' and 'power and history.' Let us consider each of these research interests in turn.

Power and Culture

Increasingly, anthropologists realized that the production of meanings is what relationships of power, myths of authority, and more formalized forms of politics and state building everywhere in the contemporary world is all about. In 1974, Abner Cohen published an important study that argued that Political Man is also Symbolist Man, that man is two dimensional. His *Two-Dimensional Man* examined the possibilities for systematic anthropological study of what Cohen described as the dialectical interplay between power relationships and uses of symbols in modern, complex, industrial societies. Yet far more influential was another book – Clifford Geertz's *The Interpretation of Cultures* (1973). Geertz's ideas about the analysis of cultural life helped to frame and shape much later work, not only in anthropology, but also in history and other academic disciplines. In 1980, Geertz published *Negara: The Theatre State in Nineteenth-Century Bali*. Here he maintained that much political analysis had been reductionist: it had ignored and silenced the significance of rituals, symbols, and meanings in the construction and reconstruction of forms of politics. The rituals of the Balinese theatre state "were what there was" (1980, p. 136); they were not means of representing power or masking its true nature – they actually constituted the state.

The 1980s and 1990s saw the appearance of a strongly intensified, interdisciplinary concern with the study of ethnicity and nationalism, especially the nation form. Anthropologists contributed by investigating nations and nationalisms as symbolic forms, as particular cultural worlds and meaning formations. An instructive example is Bruce Kapferer's *Legends of People, Myths of State* (1988), an unconventional comparison of two forms of nationalist thinking – one expressed through Australia's 'aggressively' democratic egalitarianism, the other through the sharply hierarchical thinking of Buddhists in Sri Lanka. Kapferer examined contemporary political worldviews "on their own terms and in the contexts of their ideas" (1988, p. xii). In so doing, he brought out powerfully both the enormous cultural complexity of forms of politics in the contemporary world and the way in which assumptions and perspectives derived from the heart of symbolic anthropology could be used to illuminate such forms.

Another significant anthropological contribution to the scholarship on identity politics was the anthology *Naturalizing Power: Essays in Feminist Cultural Analysis*, edited by Sylvia Yanagisako and Carol Delaney (1995). Like Kapferer, the authors of this anthology drew on fairly mainstream anthropological work on uses of imaginaries and rituals in order to shed light on forms of power differentials and authority in the contemporary world. But *Naturalizing Power* had a broader scope; it treated a whole specter of different types of self-understanding – family identity, racial identity, national identity, and religious identity. These authors argue that, although differences of identity and power often seem to be given in nature or ordained by God, they are in fact not logical extensions of a natural order, but rather an integral part of cosmologies, including myths of origins, descent, and kinship. A line goes from the classic structural-functionalists' preoccupation with the need to examine specific thinking about descent and kinship, to be able to comprehend forms of political agency, to *Naturalizing Power*'s and today's anthropologists' clearly overlapping and related interests.

Domination and Resistance

A central focus in anthropology has been how subordinate communities including minorities, for example, indigenous peoples, have been exploited, silenced, marginalized, or destroyed by ruling strata or interests – wealthy landowners, big companies, the state, and so on. This is a wholly reasonable and natural perspective in many contexts. However, in the 1980s and early 1990s, anthropologists increasingly explored

the ways in which subordinated and apparently powerless individuals and groups actively offer resistance, nonviolently, using whatever means and strategies they have access to.

A study that inspired many was James C. Scott's *Weapons of the Weak* (1985), based on field research among rich and poor in a rice-farming Malaysian village. In this book, he maintains that the response to routine domination or daily exploitation is always the subordinates' general and unremitting efforts to fight back. His eyes are fixed on a variety of prosaic weapons used by weak groups, like foot dragging, dissembling, false compliance, pilfering, feigned ignorance, setting of fires, sabotage, and desertion. Such everyday forms of resistance have often proved the most effective in the long run. This shifts the focus of analysis from open, organized (formal) activities (for example, collective stonewalling or rebellion) to what can be called the essentially unwritten and muted history of political protest. *Weapons of the Weak* goes so far as to invert the ideas of Gramsci. The latter argues that the 'radicalism' of subordinates is more strongly present in their actions than in their ideas, whereas Scott contends that the weak are most severely restricted in the sphere of behavior, while the oppressed are least shackled in the sphere of notions and interpretations, where they can safely be ventured. He underscores the necessity of never associating conformity automatically with intellectual or moral compliance, much less with legitimation.

The wave of resistance studies in the 1980s and 1990s contributed to better understanding of the dynamics of resistance, and the possible space for it, in power relations, but these studies were also met with criticism. They have been criticized for idealizing or romanticizing resistance among the poor and oppressed, and for being ethnographically 'thin': thin on the complexity of cultural meaning formation by dominated groups, and on the internal politics of those groups.

Power and History

With a growing anthropological interest in history, there also appeared a sharper recognition of the inevitable complexity, and the contested nature, of the field of power and knowledge that one calls the past. Or to put it another way, researchers increasingly took for granted that, if one wishes to understand political processes, it is necessary to examine history in at least two different manners, or to study it in two different senses of the word: first, to seek to reconstruct history according to academic criteria for history production and history writing (using archives, libraries, and so on), and second, to study the political agents' own histories, their own narratives of the past, present, and future. As many have shown, collective and individual memories are often at the core of contemporary politics. Memories give form to the practice of politics in a deep sense. Ideas about the past shape ethnic, national, and religious identities, authorize claims, and provide political leaders and masses with a horizon and a direction. Yet all narratives of the past are anchored in time. Memories reflect, and express, particular power relations and particular cultural forms and practices. The construction of stories about the past is a profoundly historical process.

An early example of a many-faceted anthropological treatment of the relationship between power and the making of history is Richard Price's classic *First-Time: The Historical Vision of an Afro-American People* (1983). The book contains a thought-provoking collection of oral testimonies about the lives of eighteenth-century Saramakas, 'Maroons' who escaped from slavery and settled in the rainforest of Suriname. Yet at the same time, the text provides a double account of Saramaka history. Saramaka communities offered Price their most secret and powerful memories. Hence, the book allows us to witness slaves escaping, surviving, and producing a new understanding of themselves in brutal surroundings. To this 'native' history, Price juxtaposes systematically a Western historical account and perspective. "Saramaka collective identity is," Price emphasizes, "predicated on a single opposition: freedom versus slavery. The central role of First-Time [their narrative of the past] in Saramaka life is ideological; preservation of its knowledge is their way of saying 'Never again'" (1983, p. 11). In a recent book, Rainforest Warriors (2011), Price tells movingly of how Saramakas continue to preserve and employ their First-Time knowledge, while they have been able, incredibly enough, to harness international human rights law to gain control politically and legally of their own piece of the Amazonian forest and secure their survival.

Tracking the Political, Reconstituting the Anthropology of the State

Today, many share Price's basic ideas about a necessary principle to be accepted for fruitful political anthropology: that political activities and struggles are not confined to a narrow set of (political) arenas, but take place in all situations where people negotiate power. Anthropologists thus seek to investigate what constitutes the political about the processes they study, but insist that politics, or the political, should not be treated as a separate category, but should be examined as connections between power relations, cultural forms and practices, and historicity. A striking change in political anthropology since the late 1980s has been the gradual emergence of a thriving new anthropology of the modern state. Most of this reconstituted and renewed anthropology of the state has been shaped by, and remains rooted in, the same ideas that I have just sketched: that is, ideas emphasizing the need to move from a focus on studies of 'politics' to a focus on explorations of culture, power, and history. In some ways there is a clear overlap between Radcliffe-Brown's conspicuous suspicion of political philosophy in the Preface to *African Political Systems* and aspects of the last two or three decades' anthropology of the state. As noted earlier, Radcliffe-Brown dismissed the idea of the state as a myth of philosophers. In contrast to this, authors of the new literature on the state take for their basis that anthropologists must study states empirically and ethnographically and take the comparative study of the state seriously. But they agree that typically philosophers, social scientists, politicians, and citizens have provided, and continue to provide, the state with an unreal concreteness. The recent anthropological literature on the state revolves around two core questions: what is the 'state,' and how can one fruitfully study it? Below the author outlines three features of this literature, before briefly mentioning a few examples of it.

The first fundamental idea behind the new anthropology of the state emphasizes that political theory, as Foucault (1980, pp. 97, 121) expressed it, needs to cut off the king's head – that is, that anthropologists should seek to unmask 'the state' and write against fetishizations of it. In an important essay, Philip Abrams stressed long ago that too much academic work has reified the state (1988, p. 76). As an alternative, he suggests that one examine the "state-system: a palpable nexus of practice and institutional structure centered in government and more or less extensive, unified and dominant in any given society" (1988, p. 82), as well as the 'state-idea,' an ideological construct "attributing unity, morality and independence to the disunited, amoral and dependent workings of the practice of government" (1988, p. 81). On the basis of ideas of this type, anthropologists have sought to answer such questions as, in what ways, and through what practices and processes, does the state appear as an objective entity over society? Through what imageries are states conceptualized, understood, and represented?

The second important idea upon which the new literature rests has to do with the understanding of the complexity of the state. According to these works, the state may most fruitfully be understood as a set of translocal institutions that are made manifest and visible in localized (or specific) practices. As Penelope Harvey (2005, p. 138) has formulated it, considering the state as 'more than' the local (or worse, as 'over' or 'above' the local, or as 'encompassing' the local) seems not very helpful. Why has this position been crucial, not to say liberating? It means accepting that researchers may produce valuable knowledge of a part of the complexity inherent in the constitution and reconstitution of a particular state-system through investigating a group of localized processes and practices, or through making an ethnography based on (localized) participant observation. Another way of putting this is to argue, as Veena Das and Deborah Poole (2004) have done, that what are often considered as the state's territorial and/or social 'margins' are not peripheral to its workings but, on the contrary, constitute manifest and prominent key features of its routine functioning.

The third major idea behind the new studies stresses the historical and cultural specificity of constructions of the state and the need for a thoroughly critical perspective on the growing, global domination of the Western conceptual apparatus. The building of modern states has typically been understood and studied within a framework that distinguishes between 'state' and 'civil society.' This conceptual distinction was created on the basis of the historical experience of Western Europe. The basic problem, however, is not that the distinction between state and civil society expresses Eurocentrism. The problem is that the separation between society, or civil society, and the state, or between the social sphere and the political sphere, does not exist in reality – not even in the West. To reiterate, the renewed anthropological research on the state claims that a modern state must be understood as produced by a broad and shifting field of power relations, everyday practices and formations of meaning. Instead of operating with a sharply confining and static starting point, the framework of a distinction between the state and civil society, one should begin by recognizing that one needs a more open conception of the state. This invites the researcher to examine in detail how a particular state is built and given shape in everyday encounters at the local level – in those contexts where the state bodies' representatives and individuals and groups interact. It is true that this makes the presence of the state in social life a good deal more fluid than is often thought. But it is precisely this fact – that the state's presence in social life really is incoherent and fluid – that makes critical, grounded anthropological work so necessary if one wishes to comprehend state-building processes.

One who inspired others at an early date to look again at the anthropology of the modern state was Michael Taussig. Through a series of thought-provoking – but also in some ways obscure – writings, first *The Nervous System* (1991) and then *The Magic of the State* (1997), he urged readers to reflect on the apparently magical powers of the state and the objectification and the fetishization of the state. Others who published important anthropological works on the state in the second half of the 1990s were Ana Alonso (1995) and Fernando Coronil (1997), writing, respectively, on the Mexican and the Venezuelan state. Since the late 1990s, two influential theorists in the discipline in general and in political anthropology in particular have been James Ferguson and Akhil Gupta. Ferguson and Gupta's coauthored, programmatic 2002 *American Ethnologist* article *Spatializing States: Toward an Ethnography of Neoliberal, Governmentality* has been enormously important. Or to put it 'more generally, these two authors' perspectives and works have, to a substantial degree, helped to define and give form to recent years' anthropology of the state, including the three key sets of central ideas listed above about the state and the study of the state. Gupta is in addition coeditor, with Aradhana Sharma, of the reader *The Anthropology of the State* (2006), a collection of historical and contemporary writings. In 2012, he published an innovative, ethnographically driven study of bureaucratic practices in India. In *Red Tape*, Gupta sees the relation between the state in India and the poor as one of structural violence that every year kills 2–3 million people. But, he argues, the country's poor are not helpless; they actively participate politically. Nor is the Indian state indifferent to the difficulties of the poor; it finances many poverty amelioration programs. Yet the Indian state care is arbitrary and irrational in its effects, he shows, and that arbitrariness is systematically produced by the very activities and projects that are meant to alleviate social suffering.

In brief, the state long ago returned as a basic concern in political anthropology, and since the late 1990s a similar shift has, in effect, occurred with a series of closely related and partly overlapping concepts or foci – such as 'sovereignty' (Hansen and Stepputat, 2006), 'citizenship' (Lazar, 2008), 'democracy' (Paley, 2008), 'authoritarianism' (Krohn-Hansen, 2009), and 'security' (Goldstein, 2010). That is, political anthropology has engaged itself increasingly in the broader academic and political conversation about globally extended uses of categories and perspectives derived from one particular, historically constituted political theory. Today anthropologists study important elements of liberal political philosophy – sovereignty, citizenship, democracy, security, and so on – but instead of approaching that tradition as if it belonged to nature, or reifying it, they deal with it as one more political cosmology, more fruitfully seen as an object of ethnographic-historical

examination than as a platform and framework for generating objective understanding.

Political Anthropology and Violence

Violence has an ambiguous status in Western thought; it often functions as a sign of (the Other's) savagery or primitiveness, but it is simultaneously a legitimate political and state means and a resource. Small wonder, perhaps, that the whole issue of how to account for and write about, or represent, violence is also a difficult challenge for political anthropologists. Classic British political anthropology, with its structural-functionalist ideas, tended to overlook violence or relegate it to the background, or else to rationalize it as functional. Such approaches have evidently helped to maintain the image of anthropologists as romanticizing and utopian. But since the early or mid-1980s, anthropology has seen a renewed and growing interest in violence, including various forms of political violence such as terror, religiously or ethnically inspired violence, and torture (Taussig, 1984; Feldman, 1991; Bloch, 1992; Daniel, 1996; Das, 2006; Kelly, 2011). The last two to three decades' anthropological writings on political violence do not represent a uniform theoretical tradition, though several shared intellectual roots are evident. But they have in common a couple of crucial features. First, these works examine forms of political violence not as incomprehensible 'exceptions' but as 'rules' – that is, not as phenomena outside a daily and ritually constructed symbolic, social and political reality of a particular kind, but, on the contrary, as practices and meanings which belong to (in the sense of being both products and producers of) a context, a society. Second, these studies analyze political violence as historically and culturally constituted processes, and as features of structures of power.

Much of the recent anthropology of the state takes it for granted that construction and reconstruction of the structures of power and knowledge that one calls modern states are inseparable from the deployment of state violence. Hence, one now has an important anthropological literature on phenomena like state terror, state massacres, and civil war (Sluka, 2000; Coronil and Skurski, 2005; Kwon, 2006; Theidon, 2013). This literature documents convincingly that state violence is used and contested in the idiom of a social formation's specific history, that such violence is shaped and energized by each society's myths of authority and identity, by each society's historically constituted cultural formations. The anthropology of modern states and violence demonstrates in addition that, as Walter Benjamin put it, testimonies of civilization are simultaneously testimonies of barbarism (1969, p. 256), and that the validity of Foucault's conceptual distinction between premodern sovereign power and modern disciplinary power is highly questionable – that his underscoring of the rationality of modernity and modern forms of power is too tidy. Foucault's dichotomy obscures too much of what should attract one's attention. The distinction is in practice blind to the violence through which states across the contemporary world reproduce the conditions of their existence, and it prevents us from fully recognizing that the roots of modern forms of power and politics, in both the global center and global periphery, lie in imperialism and colonialism.

Conclusion

In some ways, political anthropology began and ended with a set of processes occurring in a limited number of countries between 1940s and the early 1970s. But as I have shown, this is not the whole story of the anthropological study of political life. The generation of political anthropology in the 1940s and 1950s helped to define and shape views and questions which, albeit in changed forms, still remain part of today's anthropologists' investigations of political phenomena; also today's political anthropologists take it for granted that political processes and political authority can seldom be understood satisfactorily in isolation from explorations of kinship and ritual life – and that the cross-cultural study of forms of power and rule has to remain solidly rooted in examinations of everyday life and in distrust of narratives that reify or naturalize the state.

Yet at the same time, political anthropology has changed substantially. Since the early 1970s, anthropological studies of politics have generally mirrored growing and more complex interest in both meaning and history, including Western imperial histories and world history. Since the 1980s, the anthropology of politics has become less insular or strictly disciplinary, and has gradually opened itself somewhat more to forms of dialogue with interests and perspectives derived from political philosophy, political history, and political science. In so doing, it has recovered and reinforced its critical preoccupation with, and scrutiny of, the dominant categories of contemporary politics – concepts like the state, the nation, sovereignty, citizenship, and democracy.

Abstract

Political communication is an interactive process concerning the transmission of information among politicians, the news media, and the public. The process operates downward from governing institutions toward citizens, horizontally in linkages among political actors, and also upward from public opinion toward authorities.

Political communication has always been central to the electoral and policymaking process but since the early 1990s certain important developments have fundamentally altered this process, particularly postwar trends in the mass media moving from the traditional world of newspapers, radio, and television broadcasting toward the Internet. This article outlines alternative interpretations of the nature of these trends and reflects on their consequences for the process of socioeconomic and political development around the globe.

The literature in political communication can be subdivided into three major categories, using a simple systems model of the process illustrated in Figure 1 to distinguish between production, contents, and effects.

Production Processes

Work on the production process focuses on how messages are generated by political actors like parties and interest groups, and then transmitted via both direct channels like political advertisements and indirect channels including newspapers, radio, and television. Many studies have focused on the increased professionalization of political marketing campaigns in the postwar era, including the rise of the class of political consultants, pollsters, advertising executives, and their coterie, and the consequence of this process for strategic communications by political parties and interest groups. A large literature, particularly within Europe, has also studied the changing structure of the news industry, notably the economic basis of the newspaper industry and the legal structure regulating broadcasting and the press. Comparative studies have also commonly analyzed the news culture, especially the values that journalists, broadcasters, and editors employ as 'gatekeepers' in deciding 'what's news,' as well as the organizational structure of newsrooms. Recent work within this area has generated a growing body of research on the rise of new communication and information technologies, and use of the Internet by parties, new social movements, and the news media.

One of the major challenges in this subfield is to widen the scope of comparative research on a systematic basis so that we move from studies of the structure of the political communication process within particular nations to conceptual typologies, broader theories, and empirical generalizations that can be tested across different types of societies. Much of this work has traditionally focused upon postindustrial nations, particularly the USA and Western Europe, although in the 1990s increased attention has been paid to new democracies in Central and Eastern Europe, Latin America, and Asia, as well as, to a lesser extent, to the role of the news media in authoritarian regimes like Burma, China, and Cuba where the role of the free press and opposition movements remain severely restricted.

Figure 1 Systems model of political communication process.

Contents

Another related mainstream research tradition has examined the content of the messages that are produced by this process, such as the amount and tone of political reporting presented in television news, the partisan balance in the press, the coverage of election campaigns and particular events, the agenda-setting reporting of policy issues, and the representation of social minorities in the news media. The most common forms of comparison are between different media, for example, differences in the messages conveyed during an election campaign in paid political advertisements, party press releases, newspaper columns, and TV news stories.

Other forms of comparison examine trends over time, such as the coverage of political scandals or social minorities in recent decades. More rarely, collaborative teams have attempted comparison across nations, for example, concerning a specific period or event in selected major newspapers. Work in this tradition has drawn largely upon systematic forms of content analysis of a representative random sample of stories among different media, although alternative qualitative techniques for deconstructing textual and visual messages are also common. Moving beyond systematic description, which is valuable but limited, the main challenges in this area are to relate the content of the messages to either the production process (to examine their possible causes) or to their potential impact (to understand their effects).

Effects

Lastly perhaps the largest body of research, certainly in the USA, has focused at individual level on the study of the potential effects of exposure to different types of political communication messages. The most common method has been to draw upon cross-sectional or panel representative surveys or, more rarely, experimental methods. The key issues have focused upon analyzing the potential impact of exposure to different type of mediated messages (such as watching an advertisement or news story) upon either political knowledge and opinions (such as awareness about an issue, civic knowledge, or recognition of political leaders), political attitudes and values (such as support for a particular party or issue), and political behavior (such as voting turnout). Most work has focused upon the impact of the messages on the mass public or particular subgroups, like women or undecided voters, although some studies have also analyzed the effects upon middle-level elites involved in the policymaking process.

The primary challenges are threefold: (1) to expand generalizations beyond the USA, to see how far they continue to hold up within very different contexts; (2) to move beyond cross-sectional surveys, which cannot determine issues of causality, toward more dynamic designs such as panel surveys and pre–post experimental designs; and (3) to link studies of the individual-level analysis of effects to both what we know about the structure of the news industry and the contents of the messages, generating multilevel and multinational research designs. This work has made considerable progress as the study of political communications has moved increasingly into the mainstream within political science since the 1980s, but nevertheless the subfield remains predominantly US and European, and the process of internationalization in what is increasingly a global society is only starting to produce more systematic cross-national and multilevel research.

Political communication has, therefore, always been central to the electoral and policymaking process but since the 1990s certain important structural developments have fundamentally altered this process, particularly postwar trends in the mass media moving from the traditional world of newspapers, radio, and television broadcasting toward the Internet. The rest of this article outlines alternative interpretations of the nature of these trends and reflects on their consequences for the process of socioeconomic and political development around the globe.

Postwar Trends in Newspapers

Concern about traditional standards of journalism has been fuelled by major changes in the newspaper industry during the postwar era. In the USA the daily press has experienced dwindling readership and sales, especially among the younger generation, a loss of advertising market share to the electronic media, and growing concentration of ownership in larger multiple newspaper chains or a few multimedia conglomerates (McManus, 1994; Baker and Dessart, 1998). All these developments have had a major impact upon the profitability and economic viability of the print sector in the USA, particularly for smaller outlets (De Bens and Ostbye, 1998).

Yet although the demise of newspapers has been widely predicted for decades, we should not underestimate their continued popularity and technological adaptation to new forms of production and distribution. If we compare postwar trends in circulation, controlling for population growth, the evidence shows that sales of the daily press in most postindustrial societies has not been affected by the growing availability of electronic media. The long-term trend in newspaper sales in OECD countries, per 1000 population, has proved fairly stable. Average circulation in all OECD states was 271 newspapers per 1,000 population in 1950, rising modestly in 1980, before subsiding slightly to 263 per 1000 in 1996 (UNESCO). In postindustrial societies, despite the massive surge in the availability of television since the 1950s, about one quarter of the population continues to buy a daily newspaper, and readership figures are even higher. The electronic media have therefore increased the choice and diversity of news outlets and formats, but at the same time they have not killed sales of the printed press. Given growing educational levels and affluence characteristic of postindustrial societies, consumption of news has not proved a zero sum game.

Moreover there are considerable variations among societies in use of the traditional mass media. Figure 2 illustrates the penetration of newspapers and TV sets per 1,000 population worldwide. The pattern confirms how far newspaper and TV penetration levels are associated with basic patterns of socioeconomic development; use of the mass media is related to a more affluent and educated population with greater leisure time. Postindustrial societies tend to be the heaviest consumers of the mass media; nevertheless the pattern also shows considerable variations among these nations. Some outliers like the USA and Canada prove far more television-oriented

Figure 2 Worldwide distribution of newspapers and TV sets, mid-1990s. (Sources: Newspapers: UNESCO Statistical Yearbook 1997; TV sets: World Bank, 2000. World Development Indicators 2000. www.worldbank.org/data. Type of democracy: Based on the Freedom House classification of political rights and civil liberties.)

than average (along with Southern Mediterranean Europe and much of Latin America), while others nations like Norway and Sweden (along with much of Northern, Central, and Eastern Europe) remain more newspaper-oriented.

It remains unclear whether systematic trends in the newspaper industry have changed traditional journalism, producing an increased focus on crime, sex, and entertainment, as is assumed by some critics. What seems equally plausible across OECD countries is an expansion of both lowbrow and highbrow news media in recent decades, representing a diversification of the market. A recent review of the comparative literature by Kees Brants concluded that the few available content analysis studies provide an ambiguous and sometimes contradictory picture of the growth of 'infotainment' news in different countries, rather than showing a uniform pattern: 'Where for the European countries as a whole we might see a slight tendency towards the popularization of news, there is little evidence that politicians and politics are more dramatically personalized and sensationalized than before' (Brants, 1998).

Brants found that the available content analysis shows a mixed picture of the growth of 'infotainment' news in different European countries, rather than a uniform trend. Frank Esser concluded that there were marked contrasts between Germany, the UK, and the USA in the popularity of tabloid news, and that the nature and degree of competition in a particular media market is the decisive factor explaining the degree of tabloidization (Esser, 1999). Moreover systematic research on long-term trends in British newspapers from 1952–97 found that the amount of political coverage in the tabloid sector had not declined over time, as many critics assume. Instead, the tabloid press in the UK has expanded its coverage of entertainment but also maintained its political news over this period (McLachlan and Golding, 1999; McLachlan, 1999).

Therefore across all postindustrial societies newspaper circulation levels have remained largely stable during the postwar era, yet at the same time the range of papers published in these states has contracted. The number of daily newspapers published in OECD nations fell on average by 15% during the postwar era, from 160 per country in 1960 to 130 in 1996, producing greater concentration of readership in fewer outlets. Many countries have introduced measures to maintain press diversity, on the assumption that we need diverse outlets for an effective civic forum. Antitrust regulations have attempted to insure competition in the ownership of the press, for example, limiting the proportion of cross-media ownership by a single company, administered by fair trade bodies like the British Monopolies and Merger Commission or the German Federal Cartel Office. Other societies like Sweden and Norway have used press subsidies as a policy instrument to protect the financial viability of the more vulnerable sectors of the press (McQuail and Siune, 1998). Countries with provincial and localized newspaper markets like the USA and Germany proved particularly prone to media mergers and acquisitions, reducing pluralism and competition in many cities. Papers in smaller countries like Austria and Belgium also often experienced takeovers or closure because of a limited domestic market and imports from neighboring states with a shared common language.

Concentration of ownership in the hands of a few multinational corporations with multimedia empires has become increasingly common, notably Rupert Murdoch's News International, and the vast holdings of Bertelsmann in Germany, or

Fininvest in Italy (Tunstall and Palmer, 1991; Smith, 1991; Sanchez-Tabernero, 1993). Hence Rupert Murdoch, who started with two small Australian newspapers, built an empire in News Corp. that includes 20th Century Fox films, the Fox TV network, a number of US stations, 50% ownership of Sky TV, a majority interest in the STAR Asian satellite, ownership of *The Sun* and *The Times* in the UK, additional television stations in Latin America, and the book publisher HarperCollins, as well as investments in Internet companies. In the USA, Time Warner's purchase of Turner Broadcasting Systems Inc (including CNN) in 1996 created the largest media firm in the world with strong print, cable, and programming divisions. Walt Disney Company's acquisition of Capital Cities/ABC Inc for $19 billion in 1995 created the second largest media conglomerate with movie, television, cable, and Internet interests, although the purchase proved costly since ABC's profitability moved sharply into the red four years after acquisition. Conrad Black's acquisition of Southam in Canada in 1996 gave his company, Hollinger Inc, control of two-thirds of the newspapers in that country.

What will be the consequences of these developments? Many commentators like Ben Bagdikian (1997, see also Bogart, 1995) fear that media mergers have concentrated excessive control in the hands of a few multinational corporations, who remain unaccountable to the public, and that only greater economic competition can change this situation. Recognition of this problem has arisen from the understanding that economic controls can constrain the media just as significantly as political controls. There is nothing new about this concern, which was often expressed during the interwar era of the press barons when proprietors like Beaverbrook and Rothermere actively intervened to further their political ambitions. Yet others like Robert Picard (1988, 1998) remain more sanguine about recent developments, arguing that we need to distinguish between concentration defined by considering the number of media outlets held by dominant firms and concentration defined by dominance in a clear geographical market. It is the latter – which can harm consumers by producing fewer choices, poorer services, and higher prices – which is important for the availability of alternative sources of political information in a democracy.

Monopolies in the local market for ideas can be harmful for pluralism. Nevertheless it must be recognized that we need to look beyond any single media sector to establish the harmful political effects of concentration, since consumers use and have access to multiple sources of news and information, from newspapers to radio, television, and the Internet. Moreover the trends toward greater concentration are not universal, as some OECD countries have seen a significant expansion in the circulation and range of daily newspapers being published in the postwar era, particularly states like Mexico and Greece where educational and literacy rates have been rising sharply, as well as more modest growth evident in newer democracies like Hungary, the Czech Republic, and South Korea.

Trends in Broadcasting

Just as there are serious concerns about the future of newspapers, so many believe that in recent decades traditional standards of television news and public affairs have come under threat from technological and economic developments. The critical factors transforming broadcasting include the proliferation of channels on terrestrial, cable, satellite, digital, and now broadband services, fragmenting the mass audience; the crisis of identity and funding facing public service television, which once enjoyed a monopoly throughout most of Europe, following the rise of myriad commercial competitors; and lastly the more recent technological convergence with the digitization and compression of images, sounds, and data which has produced a new multimedia environment breaking down the traditional boundaries between telecommunications, the audiovisual industries, and computers.

These trends have affected all OECD countries to different degrees although their impact and timing has been strongly mediated by the existing communications landscape. In the Thatcherite 1980s, deregulation and privatization had the most profound influence on public service broadcasters throughout Western Europe (Achille and Ibanez Bueno, 1994). Following the fall of the Berlin Wall, the transition to democracy in the early 1990s produced an even more radical jolt to public television in Central and Eastern Europe (O'Neill, 1998). Meanwhile in the USA the long-standing rule of the three major networks experienced an equivalent coup d'etat, cut down in the 1980s by myriad competitors on cable and satellite (Kimball, 1994). Despite the long-standing contrasts between the commercially dominant major networks in the USA and public television in Europe, in recent years both have faced a strikingly similar multiplication of outlets and fragmentation of television audiences, raising new concerns about the standards of programming.

Despite the deluge of commercial alternatives, the public channels remain popular; on average across all OECD states public channels maintain a 42% share of the television audience. This varies substantially, however, by country. Public television RAI1 and TVE1 remain market leaders in Italy and Spain, while NRK in Norway and SVT in Sweden had most of the best-rated shows in their countries. In contrast public TV has a far smaller share in some other societies such as PBS (3%) in the United States and NHK (18%) in Japan (Mediametrie, 1999). OECD states can be classified into three major types: those that remain predominately *public* systems (based on an audience share of public channels of 60% and above), *mixed* systems (with a public share of 40–59%) and predominately *private* systems (with a public share of less than 40%). Where there is comparable data, only three OECD nations can be categorized as predominately public (Austria, Denmark and Hungary), 11 represent mixed systems, while 10 can be classified as predominately private systems. Therefore although there has been growing transatlantic convergence over the years, nevertheless broadcasting systems continue to bear the distinct imprint of their origins with radio in the 1920s, and public television continues to remain popular in many countries, rather than being swamped by commercial services.

The Rise of the Internet

Since the early 1990s the most important change to the political communication process has occurred through the rise of

the Internet, particularly in postindustrial societies that are at the forefront of the information society such as the USA, Australia, and Sweden. Networked computing and computer-mediated email have existed for the scientific elite since the early 1960s but the number of users was too small to monitor through mass surveys. The key historic development transforming the Internet into the world's favorite virtual reference library, post office, and shopping mall was a series of rapid innovations: the birth of the World Wide Web (in 1990) and the launch of popular browsers to access materials including those by Mosaic (1993), Netscape Navigator (1994), and Microsoft Internet Explorer (1995) (see Berners-Lee, 2000). Subsequent technological applications, like the easy transfer of .mp3 music files and video formats, and WAP-enabled digital telephony, while representing important innovations, cannot yet claim to have had an impact equal to the basic invention of point-and-click browsers.

As yet no official government statistics on the online population are collected by international agencies like UNESCO and the International Telecommunications Union (ITU), although many indirect measures of technological diffusion are available, including investment in scientific Research and Development, the spread of computer hardware, and the rate of telephone density. The most comprehensive worldwide guide estimating the size of the online population is provided by NUA. This organization regularly monitors and collates survey results conducted by different market research companies in each nation. The surveys ask a representative sample of the public in each country about use of the Internet from home, work, or elsewhere during the previous 3 months. NUA's database 'How Many Online' (http://www.nua.ie) currently collects data from 179 countries, covering 5.7 billion people.

The NUA evidence highlights the dramatic rise in popularity of the Internet in recent years: between 1995 and 2000 the total number of Internet users surged from about 26 to 377 million worldwide, an explosive jump within the space of a few years. The Internet became a truly global phenomenon as more and more users came online from around the world and the proportion of Americans in the online community dropped from 70 to 40% in 1995–2000. Despite this remarkable expansion, about one in 20 of the world's population was online in 2000, with highly uneven diffusion globally.

According to NUA estimates, in Spring 2000 Scandinavia and North America led the world in rates of Internet penetration, with one-third or more of the population online, followed by Western Europe, with about one in 10 online. Central and Eastern Europe, Asia, the Middle East, and South America fall below the world average, all with less than one in 20 online, while minimal diffusion is evident in Sub-Saharan Africa, with only 36 users per 1000 people. In terms of levels of human development, there are stark contrasts between rich and poor nations. Most of the world's online community (87%) lives in highly developed nations, as measured by the UNDP index (see UNDP, 1999). In comparison, the 35 societies classified by the UNDP with low levels of human development, like Nigeria, Bangladesh, and Uganda, contained only 5% of the online population, although home to half a billion people.

A finer-grained comparison of countries ranked by the online population reveals a pattern of widespread adoption in four clusters of societies:

1. Throughout the smaller Nordic social democratic welfare states, especially Sweden, Norway, Iceland, and Finland;
2. In larger Anglo-American and English-speaking nations including the USA, Canada, Australia, and the UK;
3. In the Asian 'tiger' economies of Singapore, South Korea, and Taiwan, as well as Japan; and lastly,
4. In a few smaller European nations with above-average Internet use such as the Netherlands, Belgium, Switzerland, Slovenia, and Estonia.

At the bottom of the national rankings, with less that 0.5% of the population online, few Internet users are found throughout most of the poorer countries of sub-Saharan Africa (with the exception of South Africa), as well as in many states in central Europe, the Middle East, Asia, and Latin America.

Yet at the same time if technological diffusion can be achieved in poorer societies, and it is a big 'if,' then many observers hope that the Internet will provide multiple opportunities for socioeconomic and democratic development. Digital networks have the potential to broaden and enhance access to information and communications for remote rural areas and poorer neighborhoods, to strengthen the process of democratization under transitional regimes, and to ameliorate the endemic problems of poverty in the developing world. With connectivity as the umbilical cord, enthusiasts hope that the Internet will eventually serve multiple functions as the world's favorite public library, school classroom, and medical database; post office and telephone; marketplace and shopping mall; channel for entertainment, culture, and music; daily news resource for headlines, stocks, and weather; and heterogeneous global public sphere. In the heady words of the G-8 Okinawa Charter:

> Our vision of an information society is one that better enables people to fulfill their potential and realize their aspirations. To this end we must ensure that IT serves the mutually supportive goals of creating sustainable economic growth, enhancing the public welfare, and fostering social cohesion, and work to fully realize its potential to strengthen democracy, increase transparency and accountability in governance, promote human rights, enhance cultural diversity, and to foster international peace and stability.

> http://www.g8kyushu-okinawa.go.jp/w/documents/it1.html

The Internet may allow societies to leapfrog stages of technological and industrial development. On the production side, if Bangalore companies can write software code for IBM or Microsoft, and if Costa Rica can manufacture chips for Intel, then potentially entrepreneurs can offer similar services from Malaysia, Brazil, and South Africa. The Internet encourages market globalization: small craft industries and the tourism industry in Bali or the Maldives can deal directly with customers and holidaymakers in New York and London, irrespective of distance, the costs of advertising, and the intermediate distribution chains of travel agents and retail businesses (International Telecommunications Union, 1999: p. 7; Dugger, 2000).

The Internet also offers promise for the delivery of basic social services like education and health information across the globe, a function that may be particularly important for middle-level professionals serving their broader community (Hayward, 1995; Wresch, 1996). Potentially, local teachers or community officials connected to the digital world in Lagos, Beijing, or Calcutta can access the same electronic journals, books, and databases as students at the Sorbonne, Oxford, or Harvard. Distance learning can widen access to training and education, via open universities in India, Africa, and Thailand, and language websites for schools (Arunachalam, 1999). Networks of hospitals and healthcare professionals in the Ukraine, Mozambique, and Stockholm can pool expertise and knowledge about the latest research on AIDS. Peasant farmers using village community centers can learn about storm warnings and market prices for their crops, along with employment opportunities in local towns. Where peripheral regions lack access to the traditional media, the convergence of communication technologies mean that potentially the Internet can deliver virtual local newspapers, streaming radio and television video, as well as other services.

Numerous examples can be cited to show the potential of digital technologies for fostering new opportunities for development in societies around the world (World Economic Forum, 2000). Many South East Asian nations seek to emulate the Japanese model of development in the postwar era of reconstruction, and the knowledge-based economy in Singapore, South Korea, and Taiwan. In Malaysia, for example, the Multimedia Super Corridor has been developed to bring investment from telecommunications, multimedia, and electronics companies, and the production of silicon wafers and software. The corridor has attracted major players such as Microsoft, Sun Systems, and NTT (Japanese telecom). Under the 'Vision 2020' plan, Malaysia now boasts cellular telephone penetration rates of one in every 10 people, more and more wired schools, and 21 Internet hosts per 1,000 people. Revenue generated by the production of information and communication technology goods, like office equipment, telecommunications, and consumer audiovisuals, shows that the USA leads the world but many Asian countries are close rivals, including Japan (second), Korea (third), Singapore (fourth), Taiwan (seventh) and Malaysia (eighth) (OECD, 2000: p. 24, Table 2).

Southern India is most often cited as an important area of software development, producing an estimated $3.8 billion in revenues, with this figure doubling in the last years of the 1990s. Over one-half of India's software services are exported to the USA (OECD, 2000). The Bangalore area has attracted inward investment from many major corporations, not least from the diaspora of the Asian dot.com entrepreneurs thriving in California's Silicon Valley and Cambridge's Technology Park (for a discussion see Yourdon, 1996). In rural Bangladesh many isolated communities lack landline telephones. An innovative program by Grameen Telecom supplies cellular mobile phones to village women, who rent calls in their community to repay the loan and sustain thriving micro enterprises. (By Spring 2000, over 1000 phones had been provided, serving 65000 people, and the eventual target is 40000 phones. See Richardson, 2000, see also http://www.grameenphone.com.). With this service, local communities benefit by direct links to job, weather, and health information, as well as more efficient markets for their produce. Village telecom centers are being developed with email and fax services, along with computer literacy projects in selected schools.

In Central and Eastern Europe, Slovenia, Estonia, and Slovakia have made great strides in moving their populations online, moving well ahead of Portugal, Greece, and Austria in levels of connectivity. Hungary's ambitious Schoolnet program has allowed students in two-thirds of all secondary schools to browse the Web from their classrooms, with extensive teaching resources, interactive discussion forums, events, and competitions (see http://www.SuliNet.hu). In the Baltic, the Estonian government has provided public access points for the Internet throughout the country, using schools, post offices, community centers, libraries, police stations, and health clinics. The program has been highly successful; today more than one in 10 Estonians is online, with personal computer ownership well above average for Central and Eastern Europe (UNDP, 1999: p. 64).

Progress has been slower in Africa, but nevertheless plans have been announced by Global Crossing, Lucent Technologies, and Africa One for an ambitious $1.9 billion project to link up the whole continent by 2002 through a high-speed underwater fiber optic cable, with interior countries connected through terrestrial cables, microwave, or satellite facilities, overcoming many of the current problems of the inadequate telephony infrastructure (Wired News, 2000. For further details see www.AfricaOne.com). Given a high-speed backbone, and market liberalization of telecommunication services, African nations may also be able to 'leapfrog' stages of industrialization through new technology by investing in fully digitized telecommunications networks rather than outdated analog-based systems. Cellular telephony is rapidly expanding as an alternative to conventional network services; the number of subscribers in the OECD region reached almost one-quarter of the population in 1998 (OECD, 2000: p. 81). This growth has had even greater impact in the developing world. In postindustrial economies there were 20 times as many mobile phones in 1998 as there were in 1990, and in developing economies there were 160 times as many, an astonishing rise (World Bank 2000, p. 299). Over a third of all telephone subscribers in Cote d'Ivoire, Cambodia, and Paraguay, for instance, are now connected via mobiles, a far higher proportion than in the USA (International Telecommunications Union, 1999).

The Consequences for Democracy and Democratization

What will be the political consequences of changes in the traditional news media and the subsequent rise of the Internet? In many ways it remains far too early to say (for a detailed discussion, see Norris, 2001). The Internet has generated deeply contested alternative visions about the future. Luddites fear for the worse, but technophiles hope for the better.

The most positive perspective is held by cyber-optimists who emphasize the Panglossian possibilities of the Internet for the involvement of ordinary citizens in direct democracy. In its more utopian manifestations, this view has been dubbed 'technoromanticism' (Coyne, 1999), expressed in earlier eras in

response to Samuel Morse's electric telegraph, Alexander Graham Bell's telephone, and Guglielmo Marconi's wireless radio (see, e.g., Rhodes, 1999; Pursell, 1995; Lubar, 1993). In this account, digital technologies hold promise as a mechanism facilitating alternative channels of civic engagement such as political chatrooms, electronic voting in general elections and for referenda issues, and the mobilization of virtual communities, revitalizing levels of mass participation in public affairs (see Barber, 1998). The use of the Internet by groups and social movements is often believed to exemplify digital politics.

The more utopian visions of the Internet suggest a future society in which virtually unlimited qualities of information become available, civic society flourishes, government decision making becomes more open and transparent, and nation-state borders are eroded as people build virtual communities for work, learning, and leisure spanning traditional boundaries of time and place. Although still in its adolescence, the core transformative capacities of the Internet include its potential for radically shrinking communications and information costs, maximizing speed, broadening reach, and eradicating distance. Compared with radio, television, and newspapers, controlled by editors and broadcasters, the World Wide Web facilitates a virtually unlimited choice of information and communication one-to-one (e.g., via email), one-to-many (e.g., via a personal home page or electronic conference), many-to-one (e.g., via an electronic poll) and, perhaps most importantly, many-to-many (e.g., an online chatroom), with a minimal role for gatekeepers or government censors (see, e.g., Shapiro, 1999; Weare, 2000). Internet messages have the capacity to flow further, faster, and with fewer intermediaries.

As a result many hope that recent developments, especially the spread of new information and communication technologies, will serve to undermine authoritarian regimes, creating a 'dictators' dilemma' in countries like Burma, China, and Cuba (Drake et al.). Leaders in these nations want to facilitate economic development through the Internet and yet at the same time they seek to restrict political access. It is also believed that the Internet will have major consequences for electoral democracies, countries like Russia, Taiwan, and Mexico that are seeking to consolidate democratic political institutions.

Yet as the Internet evolves, a darker vision has been articulated among cyber-pessimists, who regard digital technology as a Pandora's box unleashing new inequalities of power and wealth, reinforcing deeper divisions between the information rich and poor, the tuned-in and the tuned-out, the activists and the disengaged. This account stresses that the global and social divides already discussed mean that Internet politics will disproportionately benefit the elite (see, e.g., Golding, 1996, 1998, 2000). In this perspective, despite the potential for technological innovations, traditional interests and established authorities have the capacity to reassert their control in the virtual political sphere, just as traditional multinational corporations have the ability to reestablish their predominance in the world of e-commerce (see, e.g., McChesney, 1999: pp. 182–5). In this view, so far the potential of the Internet has failed to have a dramatic impact on the practical reality of 'politics as usual,' for good or ill, even in countries at the forefront of digital technologies (Margolis and Resnick, 2000). There are fears that continued inequalities in the spread of new technologies will exacerbate the traditional North–South divide evident in access to the traditional news media like newspapers, radio, and television. As such, while some developing countries may manage to leapfrog earlier technologies in the race towards the information society, other poorer societies may drop even further behind.

The debate between the cyber-optimists and pessimists continues and as the Internet continues to evolve over the first decade of the twenty-first century, then the impact of new technologies will become evident, whether for good (as some hope) or ill (as others fear). What is certainly clear is that political communications via the old world of newspapers and television is in the process of fundamental change and this process holds both threats and promises for the future of socioeconomic and political development.

Editor's Note

A comprehensive and current update of the literature on political communications is Esser, F., Hanitzsch, T. (Eds.), 2012. The Handbook of Comparative Communication Research. Sage, Thousand Oaks, CA. See especially the article by Norris, "Comparing Cross-border Information Flows and their Effects" (pp. 353–369). Another important resource is Norris, P. (Ed.), 2010. Public Sentinel: News Media and Governance Reform. The world Bank, Washinton, DC. Other recent and worthwhile books on the topic include Richard M. Perloff, 2013. Perloff, R.M., 2013. Political Communication: Politics, Press and Public in America. Routledge, New York and Davis, A., 2010. Political Communication and Social Theory. Routledge, London. The leading journal in this area of scholarship is the Taylor and Francis journal Political Communication, the official journal of the political communications section of the American Political Science Association. One highly relevant piece from a recent issue of that journal is Sobieraj, S., Berry, J.M., 2011. From civility to outrage: Political discourse in blogs, talk radio and cable news. Political Communication 28 (1), 19–41.

Political Ecology: Anthropological Perspectives

Bengt G Karlsson, Stockholm University, Stockholm, Sweden

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Political ecology is a transdisciplinary research field addressing nature – society interrelations, often with a focus on contentions and struggles over land and natural resources. Power asymmetries and social inequalities are critical points of departure, and many scholars in the field pursue a kind of emancipatory engagement with subalterns or marginalized people whose livelihoods depend on the local resource base. Capital accumulation and political economy more generally provide the overall framework for understanding such instances of dispossession and displacement of local communities by global forces of state and market. Political ecology has from its very inception remained a rather loosely defined research field. During the last two decades, the field has expanded rapidly. From an earlier largely rural focus, recent work increasingly engages environmental politics in urban settings and addresses contemporary questions such as climate modeling, genetically modified organisms, food industries, pollution, city planning and infrastructure development. The way ahead is for political ecology is to enter into new conversations with related strands of scholarship, like, for example, with science and technology studies, with studies that concern human – animal relations, and recent work in anthropology on ontology and radical alterity. This article aims to give a short introduction to central aspects of contemporary political ecology and its emergence.

Definition

Political ecology is a transdisciplinary research field addressing nature–society interrelations, often with a focus on contentions and struggles over land and natural resources. A commonly asked question is whose use of, claims to, or perceptions of the environment prevail. Power asymmetries and social inequalities are hence critical points of departure and many scholars in the field pursue a kind of emancipatory engagement with subalterns or marginalized people whose livelihoods depend on the local resource base. Mining, logging, nature conservation, plantations, dams, and various forms of industrial undertakings tend to encroach on and appropriate the land and resources of such communities, and these are also themes that political ecologists have been engaged with from the beginning of the 1970s onward. Capital accumulation and political economy more generally provide the overall framework for understanding such instances of dispossession and displacement of local communities by global forces of state and market.

Political ecology has nevertheless from its very inception remained a rather loosely defined research field, lacking a coherent theory. It can perhaps best be described as a perspective, approach, or research framework. During the last two decades, the field has expanded rapidly. More recent research often has an even more eclectic theoretical approach inspired by, for example, poststructuralist theory (Escobar, 1996; Fletcher, 2010), feminist and gender studies (Rocheleau et al., 1996), and science studies (Forsyth, 2003; Goldman et al., 2011). Focus has increasingly shifted to urban settings (cf. Swyngedouw and Heynen, 2003; Baviskar, 2011), addressing things as different as biomedical interventions, climate modeling, genetic engineering, fair trade commodity chains, waste recycling, machine technology, energy system, transport, and sustainable city designs. The global dimension of politicized environments remains a defining feature, and so also the concern with power and the normative persuasion for a sustainable and equitable future. Political ecology is especially influential within the academic fields of anthropology and geography and has a lot in common with other social science and humanities fields preoccupied with questions about how humans shape and are shaped by the environment (for example, environmental anthropology, human ecology, and environmental history). Political ecology is methodologically rooted in in-depth analysis of specific cases, often combining ethnographic methods with archival research, spatial techniques, and ecological analysis. The findings of the study in a particular place are commonly related to aggregated data on a regional and transnational level.

This article aims to give a short introduction to central aspects of contemporary political ecology and its emergence.

Ecosystems and World-Systems

Welcome to the Anthropocene! Scientists tell us that we have entered a new geological era where human beings have collectively become a force of global environmental change. The planetary boundaries are being pushed to the limits and as a result the most likely scenario is rising temperatures and runaway climatic changes with far-reaching consequences for people all over the world. The overall message is the urgency of the matter: the time for complacency is over. Business as usual is, in other words, not an option any longer. As one might expect, not all agree with such alarmist prognosis (cf. Hulme, 2009). Neither is this necessarily news, since a similar message has been professed by the environmental movement since the late 1960s (Milton, 1993). The difference now, however, is that the science community at large, as well as political leaders and heads of major corporations, seem to agree on the seriousness of the matter: radical measures to mitigate a burgeoning global ecological crisis are required. Yet when the world comes together to act, as in the UN conference COP 15 in Copenhagen 2009, nothing much is achieved. Individual countries push for their specific interests at the expense of common environmental action. For example, China, India, and other emerging economies in the Global South seek exceptions and insist on agreements based

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12215-9

on per capita emissions rather than gross emissions such as the US delegation pushed for in Copenhagen. The later UN climate conferences in Cancun and Doha have seemed equally impotent in crafting a powerful global framework to replace the expiring Kyoto Protocol.

In their recent book *Global Political Ecology*, geographers Richard Peet, Paul Robbins, and Michael Watts note that critical social science has been largely absent from the debates about global climate change, and hence call for political ecology to take up this challenge, calling as it were for research on global climate change "as science, policy and politics" (2011: p. 3). Such calls for the study of global nature might appear far from earlier decades of political ecology research dealing with issues closer to the ground, i.e., with peasants, herders, shifting cultivators, and other subsistence people that struggle to eke out a living in difficult social and environmental circumstances. But, as we will see, there are important continuities.

Anthropologist Eric Wolf was the first to use the term 'political ecology' with its contemporary meaning. In his article 'Ownership and Political Ecology,' a short preface to a special issue of *Anthropological Quarterly* dealing with ownership and inheritance of land in the Alps, Wolf suggested that:

> … we shall need to combine our inquiries into multiple local ecological contexts with a greater knowledge of social and political history, the study of inter-group relations in wider structural fields. (1972: pp. 204–205)

The term political ecology only figures in the title of the article, but as he elaborates, different social arrangements like ownership regimes do not follow from or are adaptions to the particular ecosystem, but need to be understood in relation to wider historical and political processes. Ecological factors matter, but to grasp aspects like access, control, or ownership of land in emerging capitalist relations, the influence of nonlocal elites is critical (ibid.: pp. 201–205). This might appear self-evident today, but anthropology was at this point in time under the influence of various forms of environmental determinism.

Wolf was a student of Julian Steward whose cultural ecology had enormous impact on American anthropology after World War II. According to Steward, the 'culture core' of a society is an adaptation to a specific ecological setting, mediated through the technology or form of subsistence of that particular society (Steward, 1955). He thought that the key question to ask in cultural ecology is how people make a living, and that once one understands the subsistence system, aspects of culture and social organization follow. Another of Steward's influential students was Roy Rappaport. In 1968, Rappaport published the much discussed book *Pigs for the Ancestors: Ritual in the Ecology of a New Guinea People*, where he applies a form of systems theory to capture the interaction of culture, in the form of ritual, and the environment. The local ecosystem is foregrounded; that which set the stage for the unfolding ritual cycle which among other things involved killing a large number of pigs. The pigs required increasing feed and labor input, and this in its turn degraded the local resource base and put enormous pressure on women who were in charge of the pigs. There is also a nutrition cycle at play where the subsequent distribution and consumption of pork served to mitigate deficiencies and with high-protein food in their stomachs people could take up fighting with neighbors, also using the pork as a bargaining stick to secure alliances and support in the warfare. Altogether this is a fascinating account of where society and environment are intertwined and function as a self-regulating system. Rappaport points to a regional system of which the Tsembaga is part, but this is not something that is given any direct importance in the study. In short, one could say that both history and the influence of the surrounding world are ignored. To recall, this was what Wolf insisted while invoking the notion of political ecology. Most commentators on Rappaport's study today would hold that his application of cybernetic systems thinking works to ignore global relations, that it reduces culture to nature, and subsequently turns human agency into systemic responses (cf. Biersack, 2006: p. 7). Even if Rappaport completely ignores Steward and in passing states that he is concerned with "*regulation*, or processes by which systems maintain their structure, rather than *adaptation*" (1968: p. 241, italics mine), *Pigs for the Ancestors* is commonly taken as the cultural ecology text par excellence. This aside, of salience here is the link between earlier forms of ecological anthropology and the political ecology thinking that started to form in the 1970s. Geographer Roderick Neumann goes so far as to claim that "political ecology is constructed primarily through the merger of cultural ecology with political economy" (2005: p. 9).

Let us briefly return to Wolf. Although he did not explicitly pursue political ecology, by insisting on the need for history in anthropology and with his concern with commodity chains spanning the world, he paved the way for later developments in historical political ecology research. Wolf's seminal study *Europe and the People Without History* (*1982*) accounts for the European expansion into the Global South and hence how the Dutch, Spanish, Portuguese, and British conquered people and territories in the pursuit of valuable raw materials. At least for 500 years, Wolf argues, we have had a world-system that affects people and their livelihoods even in the most out-of-the-way places. It is connections that are important; neither societies nor cultures are isolates. Wolf thus opens the critique against the anthropological notion of culture as fixed, internally coherent and homogeneous. This billiard ball idea of culture, Wolf argues, "must give way to a sense of the fluidity and permeability of cultural sets" (1982: p. 387). With such a critique, the functionalist idea of societies as self-regulating systems received a final blow (see Friedman (1974) for an early critique of functionalism in ecological anthropology). The systems thinking, as we will see, was not dismissed but rather relocated on another scale, i.e., moving from a local society adapted to a particular ecosystem to the world with global flows of resources and a joint division of labor.

Immanuel Wallerstein's world-systems approach is a key reference here. The modern world can be divided into countries located in the center or the core, and those in the periphery and the semiperiphery. The system works to redistribute surplus value from raw material exporting countries in the periphery to the industrial countries in the core, according to Wallerstein (1974). What we have then are systemic features that reproduce inequalities and exploitation of people in the Global South. That the former colonies gained independence in the twentieth century did not change this. Environmental

anthropologist Alf Hornborg is a contemporary proponent of historical political ecology. In a series of recent publications along with his colleagues, he elaborates the systemic properties of global capitalism and its environmental legacy (Hornborg et al., 2007, 2012; Hornborg and Crumley, 2006). A key trope in this work is that of a 'metabolic rift,' a separation of social life from nature under capitalism. Hornborg writes:

> Marx was very much concerned with the asymmetric exchange of nutrients and other material resources between town and countryside in 19th-century Europe, which among other things resulted in the impoverishment of rural soils and the accumulation of garbage and sewage in urban areas. The deterioration of European soils prompted capitalist entrepreneurs to exploit phosphates in Oceania and deposits of guano along the west coast of South America, and to develop artificial fertilizers requiring significant input of energy. Marx's crucial observation can today be expanded to the metabolism of the entire world-system (…), some parts of which are ecologically impoverished while other parts are smothered with garbage, air and water pollution and other forms of material overload (…). (2009: p. 247)

If neoclassic economic theory ignores the social and environmental aspects of market transactions, scholars like Hornborg seek to render these visible by looking at the physical properties of traded goods. Concepts like 'embodied land,' 'ecological footprints,' or 'ecologically unequal exchange' are applied for this purpose (ibid.: p. 246). Embodied land, for example, would then be a calculation of the total amount of land required to produce certain goods. Critical political ecology analysis commonly goes against the grain of global ecological governance models that are based on the idea of putting a price on nature and hence encouraging environmental stewardship through market mechanisms. The most well-known example of this is the trade of emission reductions that was introduced with the Kyoto protocol in 1997. From the political ecology horizon, market-based measures enhance the commodification of nature and alienate human beings from the biophysical realities that survival on planet earth ultimately depend on. As put by two of Hornborg's colleagues, "the social metabolism of capitalism is increasingly placed in opposition to the requirements that sustain/support natural cycles and ecosystems" (Clark and York, 2011: p. 26). What this suggests is that to tackle present environmental crises, the root causes have to be addressed. For many within political ecology, one thus has to engage the systemic features of contemporary capitalism.

What has been suggested in this section is that political ecology analysis is historical and multiscalar, looking at resource struggles over centuries spanning the local as well as the global through processes of capital accumulation.

Different Actors, Different Perspectives

Political ecology studies typically begin with a particular problem. In a pioneering study, Piers Blaikie and Harold Brookfield (1987) address the issue of land degradation. They start by noting that the etymology of the word degradation implies 'reduction to a lower rank.' But already here one has to introduce a perspective, a particular use or an interest. "One person's degradation is another's accumulation," as they famously put it (Blaikie and Brookfield, 1987: p. 14). A forest, for example, can be denuded and hence reduced to a lower rank (with detrimental changes in soil, hydrology, and microclimate), yet from the perspective of people involved in agriculture and pastoralism this can well be perceived as improvement. Different systems of production thus avail different 'capabilities' of the land. Measuring land degradation hence becomes a matter of reduced capability vis-à-vis the particular demands that are made upon the land. Such demands, as mentioned, can differ over time (ibid.: pp. 6–13). Based on such reasoning, Blaikie and Brookfield formulate the important proposition that there are "competing social definitions of land degradation" and, following from this, that there are plural perceptions, problem definitions, and rationalities to consider (ibid.: p. 16).

Blaikie and Brookfield propose that the starting point of the analysis of environmental problems should be with the land managers – those that stand in a direct relationship to the land – and that one subsequently should work one's way upward; looking at relations with other land users as well as the other social groups in the region and, on the next level, look at the state and, finally, the world economy and the various institutions operating on this level (ibid.: p. 27). They further introduced the notion of marginalization a process whereby socioeconomic marginalization pushes people into ecologically marginal areas which eventually leads into a spiraling degradation of the landscape and increasing impoverishment – "a cycle of social and environmental degradation," as Paul Robbins aptly sums up their idea (2004: p. 77). With the intensified integration in a capitalist mode of production, resource-rich margins in the global south tend to resort to environmentally destructive resource extraction, which might enrich elite groups but most often undermines the livelihoods of the majority of the local people (cf. Karlsson, 2011). The main focus, in other words, is on the connections between social and ecological change.

The research design suggested by Blaikie and Brookfield still structures much of the work in political ecology. Critical here is to map the differently placed actors involved in resource conflicts. Geographers Raymond L. Bryant and Sinéad Bailey (1997) suggest, for example, the following typology of actors that usually are present in conflicts relating to the environment: the state, multilateral institutions, business or corporate interests, environmental NGOs, and grassroots actors. It is not only the different interests of these actors that are important, but also how their respective claims are being articulated and the very basis of those claims. Here one needs to consider the different world views or perceptions of the environment that might be at play in resource conflicts. The risk here is to impose coherence on actors that are themselves internally differentiated and riven by opposing interests. Earlier political ecology has also been criticized for treating 'the state' or 'the community' as single interests. Arun Agrawal (2005: p. 211) has pointed to another related problem in political ecology analysis and that is the tendency to take actors and interests as 'already given,' hence failing to 'examine how they are made' or emerge in situations of conflict.

A recent example of a political ecology study that is aware of such problems is Paige West's study *Conservation is Our Government Now: The Politics of Ecology in Papua New Guinea* (2006). The book deals with conflicts regarding nature conservation and community development. The main actors involved are the Gimi people, who populate the forests that have become a biodiversity hotspot, and foreign conservationists seeking to preserve precious bird and wildlife habitats and then promote community development. Even if West, like Rappaport, as previously discussed, carries out a village ethnography, the focus here is on outside connections that create the place rather than the internal dynamics of the village and the local ecosystem that preoccupied Rappaport and earlier generations of ecological anthropologists. West introduces a set of outsiders who over centuries have found their way into this out-of-the-way place and who in different ways have taken part in its creation; tradesmen, colonial patrols, missionaries, scholars, tourists, Peace Corps volunteers, aid professionals, pilots, and state officials. The life of the Gimi revolves today around the small airstrip constructed at the fringe of the village, trafficked by occasional planes and helicopters that bring people and goods in and out. West also has a photo of the airstrip on the cover of her book, showing a place surrounded by forest-clad hills. Getting to the village on land requires a good one and half day's walk. The pigs are all gone, slaughtered for good as the Seventh Day Adventists have established themselves in the village, bringing along their particular dietary rules banning pork among other things. West could not even find a single pig in the settlements that constitute the village, which as she puts it, "might seem unbelievable to those familiar with Papua New Guinea subsistence practices" (2006: p. 74). Since the 1970s, people have been engaged in coffee production, which still remains the key source of income (see also West, 2012). The development practices initiated by transnational conservationist NGOs and foreign donors are based on neoliberal ideas, with the market as driver of desirable change. West focuses on two income-generating schemes in the village, both of which have turned the environment into a commodity. One is the Harpy Eagle Project which provide men with income by being guides and helping with logistic support to visiting researchers and tourists interested in the rare and exotic eagle. The other relates to handicraft production, the sale of the traditional string bag that women make out of fiber from tree bark. As West argues, the commodification of the string bags and the harpy eagle alters social relations in the village, not least gender relations, alienates people from the products of their labor and further changes their relationship and identification with the environment (2006: p. 211).

West's study illustrates well the themes and focus of recent rural political ecology writings. Besides ethnography, she builds her story on historical sources and other written documents. The process of commodification of nature and the societal changes this brings about are critical. The multiscalar dimension is foregrounded and the Crater Mountain Wildlife Management Area is represented as a place constituted through interactions of peoples, ideas, and things that span more or less the entire world. Nature or the environment might not be the subject of in-depth ecological analysis, but figures more as an arena for politics and human appropriation. Whether this is to be considered a strength or a weakness is highly contested. Critics argue that political ecology has become too preoccupied with politics at the expense of ecology and ecological processes independent of human action.

Against Political Ecology

In the article 'Against Political Ecology' (1999), ecological anthropologist Andrew P. Vayda along with geographer Bradley B. Walters launched a fierce critique against what they described as the ideologically driven and tendentious research carried out under the rubric of political ecology. In their views, political ecology is a misnomer. If the field once emerged as a reaction against 'ecology without politics' it has now become 'politics without ecology,' and thus better belongs to fields like political science, natural resource politics, or political anthropology (ibid.: p. 168). Above all, they question what they see as a priori judgments and programmatic statements that "political influences" and "especially political influence from outside, from the so-called wider political-economic system" always should be given priority. If environmental change is what one grapples with, Vayda and Walters argue, one has to begin with a careful analysis of the 'actual environmental changes' taking place, and in so doing also be open to the biophysical factors causing change (ibid.: p. 173). Geographer Peter A. Walker follows up on this point asking "Where is the ecology in political ecology?" (2005: p. 73). He nuances Vayda and Walters' critique saying that there are indeed political ecologists dealing with biophysical ecology, but that this is a somewhat threatened concern in more recent scholarship in the field.

Environmental anthropologist Eugene N. Anderson (2011) argues that the political ecology mode of analysis reduces human behavior to the pursuit of power. Particularly troubling is the tendency to invest agency in abstract entities like 'colonialism, neoliberalism, globalization,' apparently assuming that such entities make things happen on their own (ibid.: p. 59). For Anderson, the 'overattention to power' prevents anthropologists to raise other and more important questions, in his case, why certain people have proven success in surviving over millennia 'without wiping out their subsistence base' (ibid.: p. 60).

All scholarly perspectives draw attention to certain things at the expense of others. Theory guides the scholar in the selection of aspects of human or natural life to concentrate on. This is the case not only with political ecology, but scholars within this field have perhaps been more explicit about their theoretical point of departure. When Vayda and Walters claim that political ecology does not address ecology, they evoke a particular understanding of what constitutes nature or the biophysical realm. Even if most political ecologists profess a realist ontology assuming that there exists a world independent of human consciousness (Biersack, 2006: pp. 27–28, Neumann, 2005: pp. 9–10), they would commonly also align with the epistemological position that the researcher has no unmediated access to this reality. Arturo Escobar points to this (1999: p. 3) by suggesting a political ecology that strives for a 'balanced position' that acknowledges the constructedness of nature and yet purporting a realist understanding of nature as having independent existence. How to achieve this is a central problem in Escobar's excellent monograph *Territories*

of Difference: Place, Movement, Life, Redes (2008). Other scholars would probably hold that there are no alternative epistemologies of nature to consider, or for that matter any need for theoretical elaborations regarding the ontological status of the objects of their empirical investigations, that is, 'actual environmental changes.'

Ontological and epistemological debates are a mined terrain that seems to lead us astray from the concrete problems that political ecology research commonly seeks to address. Yet, these are unavoidable issues to address. Leading environmental anthropologist Tim Ingold has for some time pursued a way of thinking that questions both positivist/realist and constructivist approaches, arguing that both place the human observer outside the environment. Ingold (2000) proposes instead a view where human beings and other organisms are understood as already part of or constantly unfolding in the field of relations that constitute their environment, i.e., 'organism-in-the-environment.' Ingold is particularly interested in people's practical engagement with the world, that is, their mode of 'dwelling.' In his most recent book, he rephrases his approach to insist more on 'movement' and 'path' instead of on place, which the notion of dwelling suggests. As he puts it, "wayfaring is the fundamental mode by which living beings inhabit the earth" (ibid.: p. 12). Put differently, what is suggested here is the impossibility to think of the environment as external to the social; instead one must engage with the co-constitution of nature and society. Along similar lines Bruno Latour challenges political ecology for not questioning the conceptual pair of 'politics' and 'nature' (2004). To push the argument, Latour calls for a political ecology that lets go of nature. In doing so, he reminds us that for many of the people anthropologists study there is no equivalent of the Western category 'nature' (ibid.: p. 43). Like Anderson, Latour is also more generally wary of the preoccupation in the social sciences with power. As he puts it, "be sober with power" (2005: p. 260). In anthropology, leading scholars like Marshall Sahlins have similarly decried "the obsession with power" (for the larger debate see Gledhill, 2009). While there is reason to be wary of the mere flagging of power as the key explanatory device, much of recent political ecology analysis does offer sophisticated elaborations on how power operates in particular contexts.

Looking Ahead

In what direction should political ecology go? Political ecology is a multistranded research field and to what extent it will branch out or consolidate its core in the future is hard to tell. At this juncture, there seem to be a set of tensions that energizes political ecology. One such tension is between systemic thinking and poststructuralist or postmodern approaches that insist on difference and fragmentation. Another related one is between a firmer engagement with the biophysical or actual ecological processes on the one hand and the pursuit of narration and the discursive construction of nature on the other. Such tensions have of course a methodological equivalent, for example, a tension between a turn to more solid ecological research or toward discursive analysis. But rather than pitching the future in terms of either pathway, it is perhaps more fruitful to think in terms of political ecology entering into new conversations. An example of this is the recent call for political ecology to engage with science and technology studies (STS) (cf. Goldman et al., 2011). Earlier political ecology analysis tended to simplify science as a homogenous field of knowledge production, mainly attending to "the social interests of science (focusing on who benefits)" (Forsyth, 2011: p. 43). Bringing STS debates into political ecology can provide more sophisticated understandings of the differences and contradictions within science itself, as well as the multiple ways of knowing nature that are in circulation and that inform local resource use as well as state environmental management policy.

Another such conversation would reclaim political ecology as a central part of environmental anthropology. Pushing for this, one could follow the trail of Emilio Moran who suggests that an engaged environmental anthropology that wishes to contribute to debate about climate change has to turn to spatial approaches and apply the new tools of geographic information systems and satellite remote sensing (2011). These techniques allow for a wider reach in, for example, studies of vegetation change or land use patterns. Moran also envisions multidisciplinary research teams, rather than the solitary scholar that dominates in anthropology. As part of environmental anthropology, one could also envision a turn inward, that is, to look at the very structures of life itself and engage recent developments within biology. A critical question here is if a new figure of the human is emerging as a consequence of genetic modifications and creations of transgenetic organisms and landscapes. The work of Donna Haraway is critical here. Take the case of her call to rethink human–animal relations; a 'becoming with' instead of the human as measurement and ultimate goal of all living beings (Haraway, 2008). This can also be pushed to incorporate anthropological research on different ontologies, studies of people who endow nature with agency and consciousness. Anthropologist Julie Cruikshank gives a fascinating account of how her indigenous First Nations interlocutors portray glaciers as sentient beings that listen, smell, and are responsive to human action (2005).

But one can as well see political ecology taking a firmer grip on the political dimension of resource struggles. With the new economic giants like India and China joining the global scramble for land, minerals, and other scarce natural resources, the process of accumulation by dispossession is escalating. In the case of China, the state figures as a key agent of capitalist extraction. This happens alongside the development of new forms of neoliberal governance and control of nature. The World Bank, for example, has reinvented itself as a champion of green governance. In the case of Laos, it has managed to introduce a hybrid construct of large-scale hydropower exploitation along with the creation of a network of national parks and forest reserves. The socialist Lao government, with support from a number of transnational wildlife conservation organizations, has pursued this massive project over the heads of local communities which stand to lose their lands and livelihoods (Goldman, 2005). Global interventions in the name of saving the planet are bound to produce evermore such dispossessions. A critical role of political ecology is to insist that a sustainable future must be built on global social justice.

Abstract

Political economy emerged as a discourse in early modern Europe and reached full maturity in the first half of the nineteenth century. It is the progenitor to modern economics, but there are several distinctive characteristics that set it apart. Political economy was a literary rather than a mathematical science; it openly acknowledged its place within moral and political philosophy, and it cultivated a historical stance. It also did not draw a firm demarcation between what came to be known, *c.*1940, as microeconomics and macroeconomics. Political economy is still an acknowledged subfield within economics and political science, albeit with a different set of problems and methods.

Premodern Economic Thought

Aristotle (384–322 BC) analyzed a number of key economic phenomena in the context of his moral and political philosophy. He discerned several essential properties of money, for example, that a monetary price is a numerical ratio of two bartered goods. He ascribed three key functions to money: a measure of value, a store of wealth, and a medium of exchange. Although trade and commerce were part of Athenian life, he discredited the pursuit of profits or the practice of usury, since these rendered money into an end rather than a means to a more virtuous life.

The late medieval commentaries by Christian scholars sustained Aristotle's critical stance toward commerce, in step with Charlemagne's prohibition of all forms of usury in AD 789. To sell a good for more than the customary or just price would, in most cases, require deception and was thus a sin. Likewise, to charge interest on a loan violated the Golden Rule. If you were fortunate enough to have idle funds, then you ought to assist others. To accept more than the principal when the loan was repaid, Aquinas (1225–74) argued, was unjust because money, like wine, is a consumptible good. Money was not yet seen as an instrument for investment, since most loans were for singular events such as a dowry. Nevertheless, the discourse and the law gradually admitted exceptions to these rules. If goods were transported to a place where they were scarce, a higher price might be charged. If in the period of the loan, the lender incurred a loss that would otherwise have been averted, this might justify the payment of interest on the loan. The increasing diffusion of money, and frequent and disruptive debasements by the Crown, prompted the fourteenth-century philosophers Jean Buridan and Nicole Oresme to seek solutions to monetary instability. They downplayed Aristotle's conventional stance on money in favor of the intrinsic discipline offered by the limited supply of gold and silver. Oresme also discerned what came to be known, by the sixteenth century, as Gresham's law, by which the clipped coins drove the full-bodied coins out of circulation. The pamphlet literature of the sixteenth century tracked the transition to the legalization of usury, even though these practices were widespread since at least the thirteenth century, in the form of partnerships, bills of exchange, or annuities.

Early Modern Political Economy

In the early modern period, with the rise of overseas trade and with banking in full sway, attention shifted to stabilizing the supply of money and prices. Nicolaus Copernicus (1473–1543), Navarrus (1491–1586), Jean Bodin (1530–96), Thomas Mun (1571–1641), William Petty (1623–87), and John Locke (1632–1704) are some of the more prominent contributors, but there are hundreds more, and virtually every major philosopher of the period weighed in on economic debates. Copernicus, Navarrus, and Bodin articulated ideas that grew into the quantity theory of money, by which the influx of new money results in a rise in overall prices. Mun, a leading mercantilist and advocate of net exports as the key to England's prosperity, recognized the concept of price elasticity and, more profoundly, market forces that override legal restrictions. His short treatise, *England's Treasure by Forraign Trade* (1664), was in wide circulation till the middle of the next century. It advanced the notion of a virtuous merchant and attended to the economic rivalries between England, the Netherlands, and Turkey to control the trade of cloth and spices. Contrary to the popular view that mercantilists sought to stockpile gold, Mun downplayed the importance of money. Rather, a favorable balance of trade would provide the revenues needed to improve the manufacturing and agrarian sectors, such as the recent rise of silk production in London or the increase of arable land in East Anglia. His views on economic rivalry were boosted by mercantilist John Cary, whose *Essay on the State of England* (1695) also held sway for much of the next century.

Petty was one of the first to devise quantitative measurements of economic phenomena, including population, money supply, and per capita output. Gregory King (1648–1712), William Fleetwood (1656–1723), and Charles Davenant (1656–1714) also contributed to the discipline of Political Arithmetic, compiling data on prices and money supplies. King and Davenant discerned the law of demand, as well as the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03033-6

price elasticity of demand, with a chart of corn prices as a decreasing function of the annual yield. John Graunt (1620–74) and Christiaan Huygens (1629–95) devised population estimates and mortality tables. This in turn inspired leading mathematicians such as Abraham De Moivre (1667–1754) and Jacob Bernoulli (1654–1705) to join concepts of probability to demography, and to spell out the core elements, by 1720, of the binomial theorem or law of large numbers, an invaluable tool for statistical thinking and econometrics that took hold in the nineteenth century.

Petty and Locke, respectively, refined the quantity theory of money by devising the two additional variables of the velocity of money and the level of transactions. Given the dire shortage of specie, they each considered alternative solutions to avert price fluctuations, either increasing the velocity or altering the rhythm of rent payments. Locke was a primary influence on Isaac Newton, then Warden of the Mint, during the massive recoinage of 1696, whereby the clipped coins were summoned and replaced by full-bodied coins at par. Locke also developed a monetary theory of the interest rate, as the price for loanable funds. He urged the dismantlement of the current legal ceiling and the promotion of competitive banking such that the market rate of interest would converge on the natural rate.

Locke broached a labor theory of value that equated the labor input to the relative price. He also wedded the virtue of industry to the right to private property or estate, and motivated the individual rights of association and mobility that in turn rendered the tacit contracts of the market as the locus of liberty. Others at the time also helped forge the idea of what came to be known as the liberal doctrine of political economy, notably Josiah Child (1630–99) and Pierre le Pesant de Boisguilbert (1646–1714), who coined the term laissez faire. Their advocacy of a freer movement of goods and prices was in direct opposition to long-standing regulations and crown privileges. As finance minister to King Louis XIV, Jean-Baptiste Colbert (1619–83) had promoted the liberalization of the internal trade of France while at the same time instilling measures that would protect it against foreign imports. Colbertism was an early example of political economy in the sense in which the power of the nation-state was closely conjoined with policies for economic development in both the agrarian and artisanal sectors.

Eighteenth-Century Political Economy

In the eighteenth century, economic discourse grew dramatically. In France, the center of Enlightenment thought, there were over 3000 publications on economic topics, in the form of essays, pamphlets, dictionaries, encyclopedia entries, and full-fledged treatises. In France and Italy of the 1750s and 1760s, specialized journals, such as the *Journal Oeconomique* or *Il Caffé*, provided forums for economic debates. The crowning achievement, however, came from Scotland. Over 1000 pages in length, Adam Smith's *An Inquiry into the Wealth of Nations* (1776) became the dominant text by the 1790s. But Smith's work did not spring from a vacuum. Some key pre-Smithian texts are John Law's *Money and Trade* (1705), Jean-Francois Melon's *Essai politique sur le commerce* (1734), and Richard Cantillon's *Essay on the Nature of Commerce in General* (1755). Most influential was David Hume's *Political Discourses* (1752), a set of 12 essays on political economy that underwent 11 British editions and was translated into four other European languages, including 12 translations into French alone, all before Hume died in 1776. Ferdinando Galiani's texts, *On Money* (1751) and *Dialogues on the Grain Trade* (1769), were also widely read and cited.

There was no consensus on the name for the discourse on economic phenomena until c.1800, when political economy became the operative term. Antoine de Montchrétien issued a lengthy book entitled Traicté de l'oeconomie politique (1615), but until James Steuart's Inquiry into the Principles of Political Economy (1767), most works had titles with more singular topics such as money, taxes, commerce, or trade. Most deemed their inquiry a science, the science of commerce for example, and positioned it squarely within the broader rubric of the science of man or moral sciences. In Book IV of the Wealth of Nations, Smith introduced the science of political economy, although he defined it as the science of the legislator.

In the Scandinavian and German-speaking regions of Europe, cameralism, the science of state management or applied political economy, flourished throughout the early modern period as an integral part of higher education. Some of the more prominent contributors are Johann Joachim Becher (1635–82), Ernst Ludwig Carl (1682–1743), Carl Linnaeus (1707–78), Johann Heinrich Gottlob von Justi (1717–71), and Joseph von Sonnenfels (1732–1817). Cesare Beccaria (1735–94) was appointed the first chair of Cameral Science at the University of Milan, in 1768. Cameralism preached a strong version of autarky or economic self-sufficiency, including sumptuary laws, and promoted the study of natural history as the means to harness nature's bounty through mining and forestry.

Cameralism is usually sharply distinguished from the mainstream of eighteenth-century political economy, which was increasingly cosmopolitan and forward-looking; global trade and economic expansion implied greater prosperity in the future and, more significantly, a diminution of war and conflict. Predilections for new goods, conveniences, or luxuries, were seen in an increasingly favorable light, as the means to insure trade and thus goodwill between nations. In addition to Hume and Smith, many of the leading Enlightenment philosophers, for example, George Berkeley (1685–1753), Montesquieu (1689–1755), Voltaire (1694–1778), and Jean-Jacques Rousseau (1712–78), also wrote about economic topics, money, wealth, and trade. Two leading savants, Jean d'Alembert and Denis Diderot, secured a place for the science of economics, in their highly influential *Encyclopédie* (17 vols. 1751–65). In addition to those cited, other important contributors to eighteenth-century political economy include Bernard Mandeville (1670–1733), François Quesnay (1694–1774), Antonio Genovesi (1712–69), Condillac (1714–80), and Anne Robert Jacques Turgot (1727–81).

At Versailles, Quesnay founded one of the first schools of political economy, known as the Physiocrats or *les économistes*. Members include Victor Mirabeau (1715–89), Pierre Mercier de la Rivière (1719–1801), and Pierre-Samuel du Pont de Nemours (1739–1817). Physiocracy means the rule of nature and, as a doctrine, it advocated a strong agrarian sector with unrestricted domestic trade. All artisanal activities were deemed sterile, merely transmuting materials, leather into shoes, for

example, but not creating genuine wealth; this could only arise from the gifts of nature, the sun, the rain, and the soil that allows one seed in the spring to become two in the fall. Quesnay devised one of the first models in economic theory, his celebrated *tableau économique*, which depicted an annual diffusion of money and goods between three economic classes, the farmers, the artisans, and the landowners. The *tableau* captured the notion of capital as an advance, producing a net surplus over the course of a year. It also broached an implicit version of the multiplier by which each transaction prompted additional partial expenditures such that the initial capital doubled its output.

Hume made two enduring contributions to monetary theory: the specie-flow mechanism by which prices and money equilibrate over the entire globe; and the causal path by which an unanticipated growth in money due to a trade surplus could stimulate economic growth. Hume also advanced a nonmonetary interpretation of the interest rate and broached the law of the falling rate of profit. Although Hume's account leaves many loose threads, it is all the richer for his insights into human nature and political order, particularly as imbedded in his historical account of commercialization.

Adam Smith (1723–90) canvassed the entire field of economics, including the theories of value and distribution, trade and development, public finance, even economic history and the history of economics. Book I, on value and distribution, establishes labor as the original price of all commodities and capital goods. Labor is estimated objectively in terms of hours of exertion and subjectively in terms of the loss of leisure. Once property rights and money come into existence, capital and labor acquire returns in the form of wages and profits, respectively. The spectrum of wages can be attributed to five circumstances, and the spectrum of profits to two, the disagreeableness and insecurity of the particular business, but in both cases there exists an underlying natural rate of return. Prices are reducible to three components, wages, profits, and rent. The market price, the one observed on a quotidian basis, fluctuates around the natural or long-term price. Smith also lays out his celebrated account of the division of labor, in the sense of division within a single trade, the production of metal pins, for example, into specific tasks to glean economies of scale. He also emphasized the importance of specialization by trade to take advantage of natural talents and thus secured one of the more enduring functional relations in economics, namely, that the division of labor by trade is a function of the size of the market.

Books II and III focus on capital accumulation and economic growth, first within a nation and then with respect to global trade. Smith observes that, for most of the past, human institutions have distorted the natural progress of opulence. Instead of the agrarian surplus of a town sparking a manufacturing surplus and then overseas trade, growth was most manifest in the trading cities of Venice, Hamburg, or Amsterdam that then prompted manufacturing and finally more agriculture to feed the growth in local population. Books IV and V expand out to comparative political economy, domestic and foreign trade policies, the provision of public works, and fiscal policy. Building on Hume's account of trade, Smith delivers on the question as to why some countries are poor and others rich, and offers a dynamical account that peers far into the future.

Although mentioned only once in the *Wealth of Nations*, the invisible hand has come to be synonymous with Smith. It draws on but softens Mandeville's insight that private vices have public virtues; rather, self-interested actions not only yield unintended and beneficial consequences, but also may yield better outcomes than actions that profess the public good. The invisible hand is also mentioned once in Smith's only other book, the *Theory of Moral Sentiments* (1759), and is used in a very different light, to motivate the sense in which there is distributive justice even in a world of rich and poor. For Smith, the real purpose of life is to achieve peace and tranquility and, for the most part, this is an inverse function of wealth and rank. The poor sleep more soundly than the rich and, as long as the basic necessities of life are met, have an equal if not superior claim on a happy life. Wealth, for Smith, is a futile and hollow end, born out of a restless desire for trinkets and gadgets. But because we are deceived into thinking that wealth brings happiness, we work hard and thus keep the world in motion. Wealth also garners the approval of others, and this is part and parcel of our more fundamental disposition to cultivate fellow feeling. Arguably no one has surpassed Smith in weaving such a penetrating account of human nature into such an expansive theory of material well-being and the rise of modern commerce.

Nineteenth-Century Political Economy

Smith's ideas were extended and refined by, most notably, Thomas Robert Malthus (1766–1834), Jean-Baptiste Say (1767–1832), David Ricardo (1772–1823), and John Stuart Mill (1806–73), a tradition now known as the Classical school of political economy. The Classical economists emphasized a cost-of-production (labor) theory of value and the competing claims of the three economic classes (laborers, landowners, and capitalists) over the annual product, aptly depicted as the fall harvest of corn (wheat). The capitalists made a justifiable contribution by bringing foresight and prudence into a world that was otherwise myopic. The so-called iron law of wages proclaimed the futility of raising wages much above subsistence, since this would increase population and within 10 years increase the supply of labor thus bringing wages back to their original level. The only ways to avoid this were either to engage in the moral restraints that Malthus advocated to keep population down, or to accumulate capital, since that would increase the demand for labor.

For Ricardo, the price of the wage good, corn, was determined at the margin of cultivation, where the last units of labor and capital were deployed. Rent, which Ricardo defined as a return to the powers of the soil, was a pure residual and did not, as Smith had posited, enter into the formation of prices. Also contrary to Smith, Ricardo argued that an increase in wages was not inflationary. Because wages and profits are inversely related, an increase in wages would prompt the movement of capital from the labor-intensive (agriculture) to the capital-intensive (manufacturing) sectors, unleashing an adjustment in relative prices but not in the overall price level. Population growth implied the cultivation of inferior grades of land and diminishing returns implied the rise in the price of corn. This meant a long-term tendency for the profit rate to

fall, even if the capital stock continued to accumulate. Ricardo's analysis was exacting and cemented the method of abstract deductive reasoning. Ricardo also worked out the principle of comparative advantage in trade, predicated on the international immobility of capital. Even if a country such as Portugal can produce both cloth and wine more cheaply than its trading partner, England, it is more efficient if Portugal produces just the one good, wine, in which it has the greatest comparative advantage (lower labor costs of production) and trades that for English cloth, the good for which England has the least comparative disadvantage. Mill extended the analysis by introducing nation-specific patterns of demand and the interference effects of foreign exchange rates.

For the Classical economists, pricing came about after distribution, because the returns to the three factors of production, land, labor, and capital, were part of the natural order. Malthusian laws of population growth and diminishing returns were seen to be inexorable, the result of forces deeper than any human action or process of deliberation. Even money, via the specie-flow mechanism, was seen to have a motion that transcended human agency. This in turn bolstered the doctrine of laissez faire, most championed by Say, who argued against the possibility of persistent gluts in production, and thus for the efficiency and justice of market mechanisms. Say's *Traite d'economie politique* (1803) was one of the most widely read texts of the first half of the nineteenth century and became the target of the socialist movement that emerged at this time, led by Henri de Saint-Simon (1760–1825), Charles Fourier (1772–1837), and Pierre-Joseph Proudhon (1809–65).

Classical economists worried about the onset of the stationary state, whereby the profit rate fell to the point that capital accumulation would halt, and overpopulation result in a world of 'standing room only.' Scarcity, doom, and gloom were prevalent motifs of the dozens of texts by the Classical economists, notwithstanding the dramatic growth of the Western European economy throughout the nineteenth century. They clearly underestimated the potential for birth control, for technological inventions and innovations, both in the form of labor-saving and capital-saving procedures, and for the dramatic returns in the agrarian sector as new techniques of plant breeding, crop rotation, fertilization, and transportation took hold. The reasons for their pessimism are still not fully understood.

Early Neoclassical Economics

Despite numerous appreciations by the Classical economists of the importance of utility in the determination of prices, it was only in the 1870s that mainstream economic theorists discarded the labor theory of value and embraced the idea of marginal utility as the key determinant of a price. The leading instigators of this so-called marginal revolution were, in Britain, William Stanley Jevons (1835–82), Francis Ysidro Edgeworth (1845–1926), and Alfred Marshall (1842–1924) and, on the Continent, Léon Walras (1834–1910), Vilfredo Pareto (1848–1923), and Carl Menger (1840–1921). In the United States, John Bates Clark (1847–1938) and Irving Fisher (1867–1947) were at the vanguard. Inspiration came from Jeremy Bentham (1748–1832), who believed that utility could be quantified and all actions reduced to a calculus of pleasure and pain. Insofar as individuals strive to maximize utility and minimize labor, wealth is construed as a mental not material entity, and thus unbounded. Herein lay the germ of the more optimistic tenor that characterizes the Neoclassical period.

The most salient feature of economic theory since the 1870s is its systematic use of mathematics, particularly the calculus. Much of the original momentum to transform literary political economy into a mathematical discipline was drawn from the aspiration to emulate physics. John Stuart Mill was the first to argue that political economy must adopt the axiomatic-deductive method of Newton. What motivated the early Neoclassical economists to develop a mathematical theory was the realization that the phenomena themselves were quantitative, and that the mind deliberated in terms of infinitesimal units and thus the calculus. They drew inspiration from new developments in logic and psychology, as well as the techniques of constrained maximization as worked out in Lagrangian and Hamiltonian mechanics. Walrasian economics became the dominant theory by the 1920s, and by the 1950s, the *Foundations of Economic Analysis* (1947) by Paul Samuelson (1915–2009) insured that every future economic theorist must first acquire training in mathematics.

Political economy gained considerable standing over the course of the nineteenth century, having traditionally been part of the study of jurisprudence and moral philosophy. In 1805, Malthus was appointed to the first post as Professor of Political Economy, at the East India College, and in the 1820s, chairs were established at the more renowned universities at Cambridge, Oxford, and London. In France, Charles Gide (1847–1932) led the establishment of chairs in political economy at every French university by 1878, and founded the *Revue d'économie politique* (1887). Later efforts at discipline formation were made with the discarding of the adjective 'political' from the name of the discipline, as evident by the publication of Marshall's *Principles of Economics* (1890), along with the formation of the British Economic Society and the *Economic Journal* in 1891. Marshall's chosen successor at Cambridge, Arthur C. Pigou (1877–1959), founded welfare economics in the 1920s, and insisted that economics was now no longer tied to moral or political philosophy.

American economists garnered professional momentum with the founding of the American Economic Association in 1885, and the creation of three journals, the *Quarterly Journal of Economics* (1887), the *Journal of Political Economy* (1892), and the *American Economic Review* (1891). Thorstein Veblen (1857–1929), John R. Commons (1862–1945), and Wesley Clair Mitchell (1874–1948), among others, founded a school known as Institutionalism that left a profound imprint on subsequent American economics. Mitchell and his successor, Arthur F. Burns (1904–87), developed the National Bureau of Economic Research (founded in 1920), into the spawning ground for many of the leading American economists of the mid-twentieth century, including Burns's student Milton Friedman (1912–2006) who became the dominant voice of neoliberalism.

Marshall's most famous student, John Maynard Keynes (1883–1946), decried the problems of persistent unemployment and inequalities of wealth and income. The solution lay

with increased government intervention in the form of public works, severe inheritance taxes, and reformed fiscal policy. Keynes envisioned a world of developed economies run by decentralized institutions, whereby individuals would no longer be confined by economic necessity nor driven by greed, where they could enjoy leisure, artistic improvement, and enter the 'ambit of altruism.' In addition to his social philosophy, Keynes's *General Theory of Employment, Interest and Money* (1936) remains one of the most influential books in the history of political economy for its theoretical integration of a number of key tools and concepts, for example, the marginal propensity to consume and to save, the multiplier, the saving-investment function, and the demand theory of money. Many of these tools, including involuntary unemployment and business cycles, were worked out with his fellow economists at Cambridge, Ralph Hawtrey (1879–1975), Dennis Robertson (1890–1963), Richard Kahn (1905–89), and Nicholas Kaldor (1908–86), or can be found in the earlier work of Knut Wicksell (1851–1926). Piero Sraffa (1898–1983) and Joan Robinson (1903–83), both colleagues of Keynes, cultivated neo-Ricardian theories that drew attention to capital rigidities and imperfect competition. *Value and Capital* (1939), by Oxford economist John Hicks (1904–89), made canonical both Walrasian general equilibrium theory and the graphical tools for Keynesian economics that mapped functions for investment and money demand in terms of the interest rate and aggregate nominal income (the IS-LM diagram).

Although the Neoclassical theory became the dominant position by the 1930s, there were many alternative streams of thought, some of which still survive to this day. In Germany, for example, such thinkers such as Wilhelm Roscher (1817–94), Gustav von Schmoller (1838–1917), Werner Sombart (1863–1941), and Max Weber (1864–1920) were adamantly historical and sociological in their approach to the study of economic phenomena. Others followed Karl Marx (1818–83), such as Karl Kautsky (1854–1938) and Rosa Luxemburg (1871–1919), emphasizing class conflict, and the rights of labor to its full product. Marx's major treatise in political economy, *Das Kapital* (vol. I, 1867), was left unfinished; not until Friedrich Engels completed Volume III in 1894 was there sufficient material to spawn a distinct school. And although Marx was much indebted to Ricardo, Marxist economics is best viewed as a twentieth-century pursuit. It has become increasingly analytical and mathematical, but still adheres to some of the distinctive principles of exploitation, alienatation, and increasing immiseration. Eastern Europe produced several economists who made important analytic contributions to mainstream economics, notably Eugen Slutsky (1880–1948), Nikolai Kondratiev (1892–1938), Oskar Lange (1904–65), and Wassily Leontief (1906–99), who emigrated to the States. In England, new schools of thought were founded that were either historical or socialist in orientation. Under the inspiration of Thorold Rogers (1823–90) and Arnold Toynbee (1852–83), economic history secured a firm toehold in the university curriculum, and matured in the hands of William Ashley (1860–1927), G.D.H. Cole (1889–1959), and Phyllis Deane (1918–2012). The Fabians, notably Beatrice Webb (1858–1943) and Sidney Webb (1859–1947), founded the London School of Economics in 1895 and were instrumental in steering Britain toward the welfare state.

In Vienna, Menger attracted a number of students, including Friedrich von Wieser (1851–1926) and Eugen von Böhm-Bawerk (1851–1914), giving rise to a full-fledged Austrian School. The second generation of Austrians, Ludwig von Mises (1881–1973), Joseph A. Schumpeter (1883–1950), and Friedrich von Hayek (1899–1992), moved to Britain or the United States, and in the process created an interesting blend of Austrian rationalism with American libertarianism. Schumpeter's *Capitalism, Socialism and Democracy* (1942) and Hayek's *Road to Serfdom* (1944) are two of the most popular nontechnical works of twentieth-century political economy. Like Keynes, they grappled with the fate of capitalism as an economic system and proposed political measures to sustain the status quo.

If economics is what economists do, then the 1930s and 1940s constitute the most pivotal decades by which political economy retreated from center stage and transformed into an interdisciplinary subfield within the academy, focusing on global and comparative national development. It has been adopted by faculty across the social sciences, and given new meaning by, for example, the sociologist Immanuel Wallerstein, the political scientist Elinor Ostrum, or the economist Doran Acemoğlu. There is no simple explanation for this shift, but one critical move can be attributed to the fundamental divide undertaken by Keynes and the early founders of econometrics, Ragnar Frisch (1895–1973), Jan Tinbergen (1903–94), and Trygve Haavelmo (1911–99). They segregated macroeconomics (the study of national output and growth) from microeconomics (the study of prices and markets) and political economy took on a more specialized and subservient place in the configuration of economic theory.

Political Economy in Anthropology

Abstract

The term *political economy* has been used by anthropologists since the 1970s, particularly in North America, to signal a shift in the focus of anthropological analysis away from isolable local communities and toward large-scale regional political/economic systems, along with the adoption of broadly Marxist, or at least materialist, theoretical frameworks. In this article, the field is also taken to include the field of Marxist anthropology based mainly on the work of French structural Marxists, which emerged in the same period. Although both Political Economy and Marxist anthropology have fallen out of favor in recent years, many of the concerns of the 1970s have returned in the more recent critical engagement with globalization and neoliberalism and in new work on the anthropology of money and finance and the ethnography of capitalism.

Introduction

In the history of economics, political economy is a widely accepted designation for a general style of analysis of national wealth and international trade that emerged in the early nineteenth century in the writings of classical economists like Adam Smith and David Ricardo. The term was borrowed by anthropologists in the 1970s, and mainly in North America, to signal a shift in the focus of anthropological analysis away from isolable local communities and toward large-scale regional political/economic systems, along with the adoption of broadly Marxist, or at least materialist, theoretical frameworks. Particularly in North American anthropology, political economy took 'the form of studying the effects of capitalist penetration upon these communities' (Ortner, 1984: 141).

Doubtless, American efforts in this direction were distinguished by their debt to the work of dependency theorist Andre Gunder Frank and that of the sociologist Immanuel Wallerstein on the capitalist world system, as well to the influences on them of earlier materialist trends in American anthropology. However, it would be misleading to see this shift as being limited to North American anthropology in the 1970s. At least some anthropologists were already analyzing the effects of such broader links well before 1970, while contemporaries outside North America were often well in advance of their American colleagues in the development of Marxist approaches to anthropological materials.

Notably in France and Britain, and often under a rather different set of theoretical influences, most notably from contemporary Marxist theorizing, anthropologists also began to examine the relationships between capitalism and what were often described as precapitalist modes of production or social formations in Asia, Africa, and Latin America.

Any assessment of the general move on the part of anthropologists of the 1970s to engage with global economic factors and their influence on the local groups they were more used to studying – and to do so from a broadly Marxist perspective – must then examine developments outside American anthropology as well, even if they may not have attracted the label of political economy.

Political Economy, Anthropology, and Global Capitalism

The development of political economy in North American anthropology was linked to a more general intellectual and cultural challenge in America's imperial expansion, itself stimulated by opposition to the war in Southeast Asia. Consequently, political economy in the American context was on the one hand theoretically somewhat eclectic and, on the other, concerned primarily with issues of global capitalism. Given the tendency of anthropologists to engage with regions, societies, and cultures outside or on the margins of North Atlantic capitalism, much of the energy of political economists in America was devoted to analyzing the impact of capitalism on individuals and communities on what were sometimes called, following Wallerstein, the 'peripheries' of the world capitalist system. This global emphasis in their approach to more traditional anthropological concerns, moreover, made American political economists less likely to classify these marginal individuals and groups as precapitalist. They were consequently also less interested than their French counterparts in any attempt to develop a theory of modes of production that was general and comparative, seeing it to be of little relevance to the concerns of social and cultural anthropologists doing field studies in the present.

As already noted, materialist analyses were well established in American anthropology before the emergence of political economy, although it could hardly be argued that these analyses were based on any genuine engagement with, or even sympathy for, the work of Marx himself. This materialist current is commonly associated with the name of Leslie White, who is assumed to have been familiar with work in the Marxist tradition, if not with Marx's own writings, although he was prevented from acknowledging the link explicitly because of a generalized American hostility to Marx. Marvin Harris was an influential advocate of materialist analyses from the 1960s, although unlike White he was openly hostile to Marxist theorizing, preferring a form of techno-ecological determinism that was rather close to that of White.

Closer to the interests of the new generation of political economists was the work of Julian Steward, who had

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12132-4

formulated a more open multilinear theory of evolution. He also headed the Puerto Rico project, which was unusual for the ways it tackled issues to do with social change and colonial history as central concerns of anthropology.

But more than anyone else, a group of anthropologists studying in New York in the 1940s – including subsequently well-known figures such as Eric Wolf, Sydney Mintz, Elman Service, and Stanley Diamond – became the key figures in anthropology's direct engagement with colonialism and global capitalism from within a materialist perspective, an engagement that subsequently attracted the label *political economy*. Wolf and Mintz, in particular, became increasingly concerned with the implications of European global expansion for the anthropological analysis of peasant communities in the Caribbean and South America. Both wrote anthropological monographs that were unusual for their discussion not just of local systems of culture, kinship, and social organization but also of the formative links established in the long history of European colonization between local communities and the centers of the world economy in Europe and North America. Later, both also produced influential general works concerning the development of a world capitalist system, paying particular attention to the interconnections established in this process between Europe and North America on the one hand, and on the other hand, the only apparently isolated peoples on its periphery (Wolf, 1982; Mintz, 1985).

Others, both from the New York group and outside it, contributed, if less directly, to the development of political economy. Unlike many materialists in American anthropology, Stanley Diamond made important contributions in Marxist theory, founding the journal *Dialectical Anthropology* in the 1970s and working on a critical/phenomenological Marxism that contrasted rather sharply with contemporary Marxist theorizing in France.

Mention must also be made of Eleanor Leacock, who made her own contributions to the development of a Marxist anthropology through the pursuit of the themes of kinship, family, and gender raised in Engels' *Origins of the Family*, as well as to political economy in some important work on the impact of the fur trade on indigenous North Americans.

Two further influences served to broaden the popularity of such analyses in American anthropology by the early 1970s. First, as noted, there was the publication of the very influential early works of the dependency theorist Andre Gunder Frank and, shortly thereafter, the works of sociologist Immanuel Wallerstein (see Frank, 1969; Wallerstein, 1974). What these works brought, in particular, was a more sophisticated analysis of the imperatives of the global economy and the compatibility, indeed even the functionality, within it of apparently noncapitalist economic and political forms. Anthropologists like Jane and Peter Schneider, Katherine Verdery, Gavin Smith, Carol Smith, William Roseberry, and others associated with the new political economy school did not necessarily accept wholeheartedly the capital-centrism of these more global approaches, but they did enter into a sustained and fruitful debate with them over the global versus the local determinants of socioeconomic systems in the so-called Third World as well as in the European semiperiphery.

The second formative influence on materialist anthropology in America in this period was, of course, the growing movement against America's military intervention in Indochina. This contributed greatly to the radicalized political and intellectual atmosphere on North American campuses, where a new generation of anthropologists was being trained. But it also has specific implications for anthropology, raising as it did the possibility that the discipline itself could be implicated in the project of empire. In 1968, in an article that generated a heated debate, one anthropologist went so far as to describe anthropology explicitly as a 'child of imperialism' (Gough, 1968). Similar concerns led to significant conflicts within the professional anthropological body itself (the American Anthropological Association), which debated the involvement of anthropologists in covert operations at its annual meetings.

The French Marxist Heritage

If in North America the main parameters of political economy were laid down by the engagement of anthropologists with a predilection for materialist explanations, with issues arising out of the development of a world capitalist economy, in Europe the situation was somewhat different. This is not to say there was no interest in the relationship between global capitalism and local socioeconomic organization. On the contrary, this central concern in American anthropology found important parallels, especially in France and Britain. There, however, the debates were informed by a far more rigorous attempt to develop a Marxist theory appropriate to the analysis of anthropological materials, a level of theoretical concern largely absent in contemporary American anthropology. And the center of this reworking of Marxism was to be found in France.

Developments in French anthropology were subject to three distinctive influences. The first was the opening up of the Marxist left, spurred in part by the developing Marxist critique of Stalinism which, among other things, produced a space for Marxist intellectuals, both inside and outside the Communist Party, to criticize the kinds of mechanical and evolutionist interpretations of Marx that until then were the only versions permitted by Marxist parties. Second, and related to this, the Sino-Soviet conflict inspired at least some Marxist intellectuals and political activists to search for alternative models of socialism and of the ways in which it could be achieved. Third, French anthropology was dominated by the imposing intellectual figure of Claude Lévi-Strauss, so it is not surprising that when French anthropologists turned to the work of Karl Marx for inspiration, they developed a structural version of Marxism that was highly critical of the existential and humanist Marxism whose best-known exponent was Jean-Paul Sartre. It is not surprising that the two main schools in French Marxist anthropology – the first associated closely with the theories of the communist philosopher Louis Althusser, the second with the structural Marxism of Maurice Godelier (a student of Lévi-Strauss) – although critical of mainstream 'mechanical Marxism,' should both also have been equally if not more critical of the main alternative. These ideas may not have been particularly influential in the wider student movement, but Althusser's anthropological admirers, most notably Emmanuel Terray and Pierre Philippe Rey, along with Godelier and his students, all sought to reformulate a Marxism that was

'scientific,' based on Marx's 'mature' work, and avoided what they took to be the pitfalls of an approach based on assumptions about a universal human subjectivity thwarted by capitalism.

As this suggests, structural Marxists rethinking the Marxist heritage had to go back to the work of Marx on capitalism, and what they found in so doing were the beginnings of a general theory of historical materialism within which anthropology could play a very significant role. That role was to be the formulation of a general theory of modes of production and the laws of transition from one to another. As opposed to the thinking of some of their critics, this was not seen as a mere exercise in antiquarianism because such a theory would provide, it was argued, the theoretical basis for a political practice aimed at stimulating not just a transition to communism but the shaping of the nature of the communist future as well.

It has been suggested that there was no single Marxist approach in French anthropology but instead, a collection of competing and often antagonistic camps. Yet in spite of differing allegiances – to Althusser, to Godelier's version of structuralism, and so on – at least when viewed from the outside, French Marxist anthropology did seem to constitute a fairly unified discursive field for debate.

French Marxist anthropologists made important contributions to a number of areas of concern to both Marxism and anthropology (for an overview, see Kahn and Llobera, 1981). A good example is provided by the debates over the nature of lineage-based societies in Africa that were sparked by the early publications of Claude Meillassoux (see, for example, Meillassoux, 1964, 1967). Scholars, including most centrally Meillassoux himself, Emmanuel Terray, and Pierre Philippe Rey (both former students of Louis Althusser), as well as Maurice Godelier, Arienne Deluz, Pierre Bonte, and others used Meillassoux's material on the Gouro of the Ivory Coast, as well as ethnographic data on other uncentralized African societies, to debate most of the basic concepts of historical materialism – class, mode of production, productive forces and relations of production, exploitation, articulation, social formation – as well as the central theoretical tenet of historical materialism – economic determinism (or what one participant called Marx's hypothesis of economic determinism in the last instance). This important debate, more than any other, serves to illustrate much of the potential theoretical benefits, as well as some of the main pitfalls, of the project of a Marxist anthropology as it was conceived by these scholars, namely a project to recover, by means of a careful reading of Marx's own work, his 'mature' theoretical project and to examine its more general validity in situations largely unknown to its originator. Moreover, the debate added considerably to the understanding of more traditional anthropological problems related to the nature of authority and social cohesion in kinship-based societies and societies without centralized political systems.

Noteworthy in this context were the critiques of a number of feminist anthropologists, including Felicity Edholm, Olivia Harris, Kate Young, and Maila Stivens, who built on the Marxist concept of social reproduction to generate important insights into gender inequality in precapitalist as well as capitalist societies.

Marxism, Articulation, and Political Economy

From the perspective of the study of the linkages between global capitalism and local social and economic systems, the most important effect of these debates was in contributing to the formation of a theory of what some called the 'articulation of modes of production.' Drawing on the theoretical work of Althusser himself, Etienne Balibar, Maurice Godelier, anthropologists, and others with an interest in the concerns of political economy produced analyses of the relationships between the local and the global, which were understood as an articulation of capitalism with different precapitalist modes of production. It is not often appreciated that exploring this relationship was always a central concern of Meillassoux in a series of publications, including his early monograph on the Gouro. A sophisticated Althusserian analysis of articulation is to be found in the work of the brilliant Marxist anthropologist Pierre Philippe Rey (see especially Rey, 1973). And other important contributions to this project were made in Britain by a variety scholars influenced by French structural Marxism, including Ernesto Laclau, Barry Hindess, Paul Hirst, Talal Asad, and others, and by a group associated with the journal *Critique of Anthropology*, including Felicity Edholm, John Gledhill, Olivia Harris, Joel S. Kahn, Josep Llobera, Stephen Nugent, and Maila Stivens. Mention should be made also of the important work of Jonathan Friedman on Marxist theory, anthropology, and globalization.

Beyond Political Economy

The central concerns of political economy have certainly not disappeared in anthropology. But it would be fair to say that in general there have been significant shifts at the levels of theory and of analytic style as well as in the selection of problems and issues for research, such that very few anthropologists now describe themselves as political economists. The reasons for this declining popularity of political economy are varied. They certainly include an acknowledgment that earlier attempts to theorize the relationship between the global and the local in either a dependency/world systems mode or by means of a concept of the articulation of modes of production suffered from problematic theoretical tendencies. These included an overly functionalist understanding of the needs of capitalism, a unidimensional productionism (or economism), an inattention to the spheres of meaning and agency, and so on. Political economists have, like many others, been criticized for their eurocentrism, for their inattention to gender as a primary category of sociocultural differentiation, and for failing to appreciate that race, culture, and gender are not mere epiphenomena of social systems. Like those of many others, the claims of truth by political economists have been subjected to wide-ranging critique by scholars influenced by poststructuralism, postmodernism, feminism, and postcolonialism.

Social and cultural anthropology, in particular, was also affected by the critiques of those associated with the so-called writing culture school, which undermined claims about the reality of those other lives constructed in anthropological texts and led to a demand for greater degrees of reflexivity. Political economy which, despite the name, doubtless focused on

economic issues more than any others, was naturally affected by these shifts. Finally, European versions of political economy, precisely because of their greater concern with issues of (Marxist) theory, have been damaged by the general intellectual and political rejection of Marxism, particularly since the late 1980s.

Although political economy in the various forms it took in Europe and North America in the 1970s and early 1980s will probably not regain the central role it once had in the discipline, for better or worse, it would be wrong to pronounce it dead and buried. The tendency to see in the rise of Foucauldian and poststructuralist paradigms a complete rejection of, particularly, the basic conceptions of structural Marxism is probably misleading. It is possible to argue that these merely took the structural Marxist project one step forward, from a critique of ideology to a critique of discourse *tout court*.

Certainly, some of the central concerns of political economy have re-emerged in more recent attempts by anthropologists to theorize the phenomenon of globalization. An anthropology seeking its roots in a variety of new social movements is very much on the agenda of anthropologists styling themselves as radical and/or committed. Some of the concerns of an earlier generation of political economists are evident in more recent feminist anthropology as well as in various attempts to construct an anthropology of human rights. Recent attempts to forge a link between critical social theory and anthropology through various reworkings of the concept of modernity may be seen as an attempt to correct the perceived failings of structural Marxism. There are even calls for another return to Marx.

The Critique of Neoliberalism

Perhaps the field in which the concerns of the political economists have most clearly reasserted themselves in the new century has been that of the largely critical analyses of so-called neoliberalism. To quote one contributor to the field: "Across the globe, policies called neoliberal have had devastating impacts on the people with whom anthropologists work. Referring to neoliberalism has become a shorthand way of signaling all that is wrong with the ethnographic present, much as previous generations of anthropologists would refer to globalization [and, one should add, their political economist predecessors would refer to capitalism]" (Elyachar, 2012: 76) (Just how central the critique of neoliberalism has become to the discipline is evident in the fact that two of the most important anthropology journals in North America and Europe, respectively, devoted special issues to the topic in 2012 (Cultural Anthropology 27, (1) and Social Anthropology 20, 1)). Particularly influential have been the writings of anthropologists James Ferguson and Aihwa Ong, along with those of geographer-turned-anthropologist David Harvey (see for example Harvey, 2005; Ferguson, 2006; Ong, 2006).

Originally coined in the interwar years by the Viennese economist Frederich Hayek to signal what he thought were the failings of classical liberalism, as well as his implacable opposition to state involvement in economic planning, the term *neoliberalism*, as used in turn-of-the-century anthropology, means somewhat different things to different people. For some it refers simply to the triumph of unfettered market forces, along with the corresponding decline in the powers and economic role of the state, that appear to date from the Reagan-Thatcher years. Others, however, have suggested that the neoliberal era has not been characterized by the sort of withdrawal of the state favored by both free-market radicals and libertarians, but instead by what Loïc Wacquant, based on research on Chicago's South Side and the housing projects of outer Paris, has called a new 'articulation of state, market and citizenship that harnesses the first to impose the stamp of the second onto the third' (2012: 66). Wacquant's formulation, in which structural links are posited between commodification, disciplinary social policy, penal policies that are 'expansive and pornographic,' and the 'trope of individual responsibility,' has the advantage of theoretical rigor and therefore the advantage in explicating what is actually 'neo' about neoliberalism. However, it can be criticized on very much the same grounds, as were earlier attempts at theorizing the capitalist mode of production as a structure in dominance of three semiautonomous levels, or instances, namely, that when juxtaposed with the global diversity of actually existing neoliberal regimes, the necessity of the connections among these elements is called into question (see, for example, Hilgers, 2012). Like the abstract concept of the capitalist mode of production, in other words, the more rigorous formulations of a concept of neoliberalism become extremely difficult to operationalize in precisely those contexts in which anthropologists work.

Toward an Anthropology of Capitalism

If the critical anthropological analyses of neoliberalism build on political economy's concerns with the impact of (global) capitalism on the individuals and communities they study, the development of what could be loosely termed an anthropology of capitalism based on the mainly ethnographic study of capitalists themselves has served to flesh out the somewhat abstract or reified understandings of capitalism that prevailed in political economy.

It is impossible to do justice in a short survey to the full range of contributions to this emerging field, but it certainly includes ethnographic studies of corporate life, such as those by Patricia Sloane-White in Malaysia (Sloane, 1999). Another area in which a good deal of innovative work has been done is the ethnographic study of banking and finance. The ethnographic study of financial institutions was pioneered by scholars like Mitchel Abolafia (Abolafia, 1996), while more recent contributions include the work of Caitlin Zaloom on futures markets, Karen Ho on investment bankers, and Alexandra Ourousoff on Wall Street (Zaloom, 2006; Ho, 2009; Ourousoff, 2010). The scholar who has probably done the most to establish the study of finance in the discipline has been Bill Maurer (see Maurer, 2005, 2012).

Historical and Comparative Political Economy

The broadly comparative and historical projects of at least some of 1970s political economy have not disappeared, although they have involved a turn toward theorists other than Marx, or at least a blending of Marxist and non-Marxists

theoretical approaches. With his research on Islamic finance, Maurer himself, of course, retains something of the political economists' comparative project. But perhaps closer to the project of the historical materialists is the broadly comparative and historical work of anthropologists like Keith Hart on money and markets, C.M. Hann on property relations, and David Graeber on value and debt. Although to different degrees remaining within the Marxist tradition, such scholars have also reached out to non-Marxist theorists and traditions: Marcel Mauss and Karl Polanyi in Hart's case, classical anthropological work on property as a bundle of rights in Hann's case, and the anarchist tradition in Graeber's case (see Hann, 1998; Hart, 2001; Graeber, 2011, among others).

Many of the concerns of those anthropologists who were content to be labeled political economists, or even Marxist anthropologists, in the 1970s are of continuing importance to the discipline, even if very few would use either of these terms to describe themselves today. It is therefore, perhaps, premature to pronounce political economy in anthropology dead and buried.

Political Economy of Renewable Energy

Volkmar Lauber, University of Salzburg, Salzburg, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Renewable power from wind, solar PV, or biomass reached market penetration with large full-scale deployment within about four decades of the first oil crisis. This required overcoming ideological hurdles and electricity incumbents' vested interests. Chief ideological hurdle was neoclassical economics with its restricted role for public policy in technology innovation, thus policy initiatives came about in only a few countries with special political constellations. EU institutions reflected those conflicts; their renewed intensification in the 2010s led to a setback for renewables in Europe. But by then the breakthrough on costs put renewables in a good position to thrive on all continents.

Introduction

Overcoming fossil fuel dominance in electricity generation by a shift to renewable energy sources is a long-term social and political process as well as a technological and economic one which began about four decades ago. Actors from very different milieus and worldviews need to be won over to this idea before it can become effective and prevail over defenders of the status quo, above all interests linked to fossil fuels. The present article analyses how renewable electricity generation made its breakthrough over the past two decades due to special policies mostly in Europe and the United States, and how Europe may now fall behind again on this development.

An Idea Emerges and Gains a Foothold

The idea to shift from fossil to renewable energy usually appears at times of crises resulting from increasing fossil fuel scarcity, higher prices or difficulties with imports, or from the hazards resulting from fossil (or nuclear) energy use. Renewable technologies can avoid these problems while promising greater self-reliance and an energy system more responsive to citizen concerns. In recent years, the strongly reduced cost of renewable power became an additional argument.

Many of these things came together in the 1970s. For the United States, geologist M. King Hubbert had predicted in the 1950s that oil production would peak in the 1970s; the Club of Rome in its first report on the Limits to Growth in 1973 spread a message of a broader resource scarcity coming up. When the first oil crisis broke out in 1973, OPEC's oil price increase and embargo for the Unites States gave Americans a first impression of energy scarcity (more for heat and transport though than for electricity). Around that time the cost of nuclear power plants in the US was also becoming prohibitive, and nuclear power suffered another severe setback with the Three Mile Island accident of 1979. All this contributed to reconsider energy technologies and helped the 'discovery' of renewable energy. The energy crisis put pressure on governments to set initiatives on this issue. Civil society also reacted, often in ways quite different from governments.

Nuclear power had become a collective myth of progress in the 1950s but made slow headway until the energy crises of the 1970s when many governments formulated plans for its rapid expansion. In several countries, this led to a strong antinuclear movement (Germany, France, Denmark, Austria, to name but a few). In Germany and Denmark, support for 'solar' energy in architecture, home heating, and electricity generation became part of an energy counterculture which was quickly taken up by the media and public opinion. More in the background, reliance on coal was also stepped up to replace oil. Electricity from wind, biomass, and solar power was still an abstract idea rather than an embodied technology, but it started to draw attention. This was hardly a case for business entrepreneurs as potential profits were uncertain and far away; thus progress seemed to demand government support, and this is where most calls were addressed. Many organizations such as universities, research organizations, and high-tech firms were eager to move into this field with the help of public funding.

Surprisingly, private initiatives came into being nonetheless, notably with 'tinkerers.' In Denmark, they were the pioneers on wind energy, often coming from the cooperative and folk high school movements; in Germany they pioneered work on biogas plants and to a lesser extent also on wind energy. Unlike business actors, they shared inventions freely without regard to patents, even across borders. They mostly came from the antinuclear counterculture and social movements.

Government Ambivalence: Subsidies for Nuclear and Coal, R&D Funding for Renewable Energy

The U.S. government was the first to react in big style to the oil crisis of 1973/74 with the creation of a well-endowed new government department (which became the Department of Energy in 1977) and comprehensive R&D programs. Though the main emphasis was on coal and nuclear power, generous R&D funding for wind and solar power was expected to bring down their cost quickly. Several prototypes of wind turbines were developed and demonstration programs started. The cost of solar cells was also brought down substantially. In 1978, a federal law (the Public Utilities Regulatory Policies Act, PURPA) was passed which required utilities to purchase renewable electricity from qualifying facilities at the avoided cost of own power. Half a decade later – probably unexpected

for the law's authors – this act unleashed remarkable business entrepreneurship in the field of wind energy during the California wind power boom in the early 1980s which started under governor Jerry Brown, supported by favorable tax credit legislation, and led to the first mass market for (mostly Danish) wind turbines. But the big spending programs for R&D and RD&D programs were wound down again when Ronald Reagan replaced Jimmy Carter in the White House and turned the focus back to oil and gas; Republican governor Deukmejian in California brought a similar change (van Est, 1999).

In Europe, no government undertook such a drastic step as PURPA in the 1970s or even the 1980s, but things changed there as well. Most governments stepped up R&D on renewable energy in the second half of the 1970s, to reach a peak in 1980 followed by decline thereafter; as in the US this support remained tiny when compared to that given to nuclear power. Nevertheless, several governments funded the development of wind turbine prototypes (Belgium, Denmark, Germany, the Netherlands, Sweden, the UK), usually large machines full of technical problems. The idea prevailed that utilities would be the natural users of such turbines, even though utilities were quite ambivalent about new and decentralized renewables (in Germany a 3 MW turbine was even built with public money to prove that wind power was no viable alternative to nuclear). Only Denmark and Germany also supported small turbine development; these were the first viable machines. In the UK, wave power was also subsidized, particularly in a big project that literally sunk in a storm. Solar power research took place in fewer countries; Germany was leading as German firms had been producing PV for U.S. satellites for two decades. In the 1970s, some high-tech firms thought that a breakthrough to cheap solar power could be achieved quickly but lost interest when things turned out otherwise.

By the 1980s, government R&D had produced a variety of prototypes still far removed from market readiness and with only few niche markets (there was one for small wind power among a community of believers in Denmark) and tiny specialty markets in which prices were not that important (e.g., off-grid applications for PV such as buoys, telecommunication towers, or pipelines). But on the whole, those prototypes could not generate electricity at prices competitive with fossil generation. Only Danish wind turbines – smaller and sturdier than most others, built on earlier experience and with state quality control – for some years found a sizable market in California until the boom ended in 1984 with the termination of PURPA standard offer contracts. Voluntary green electricity markets could not create sufficient demand. Change became more urgent with the Chernobyl accident in 1986 and the emergence of climate change as a major political challenge; both called for a reconsideration of fossil and nuclear (fission) electricity.

Yet for adherents of neoclassical economic theory – the dominant economic theory of public management, reinforced by the new neoliberal ideal of lean government – the state had no legitimation to go beyond providing R&D and perhaps also RD&D support; for them, things were now up to the market. In practice, this attitude would have left the prototypes in a lurch, with market actors – and particularly utilities – shying away from costly adventures. In general the utilities – but also most governments and the IEA (International Energy Agency) – viewed renewables as simply too small to be taken seriously before the middle of the twenty-first century, their potential too marginal under the meteorological conditions of Europe and their price too high. This is precisely what happened with most prototypes. It took some 'political accidents' to allow the necessary next step in renewables development in at least a few countries: systematic market creation for renewable power. This inspired considerable political controversy.

The Issue of Market Creation: by Whom, for Whom, and by What Instrument?

Mobilizing public resources to help firms to be viable is more easily associated with declining sectors than with learning investments for young industries, at least in the 'advanced' industrial countries (even though it was practiced as development economics in the 1970s in the 'newly industrializing economies' of Southeast Asia). In European states, such decisions were usually made by the Finance or the Economic Affairs ministry – at that time mostly strongholds of neoclassical economics for whom supporting a technology beyond R&D and a prototype was not considered useful since at this point it was up to the market to take over. Exceptions were made in cases of high politics for reasons of national priority such as nuclear power programs or even coal subsidies (to secure an important domestic energy source). But fledgling renewable power technologies hardly belonged in this category.

In some states, parliaments, more responsive to social movements than bureaucracies that often identified with electricity incumbents, took on the cause of renewables against this orthodoxy. In some cases, breakthroughs came about as a result of a political accident that let a bill slip through parliament before the electricity incumbents had mobilized their supporters.

One such case was the first instance of market creation for renewables which took place in the United States with PURPA 1978 (see above) and which was not expected to play a big role for renewables but helped – together with tax credits – to set off an unprecedented boom for wind power in California. But the tax credits were problematic: investors received the credits once a turbine was installed, even if it failed shortly afterward. Thus the standard offer contracts for investors under PURPA were terminated in 1984 and the wind boom stopped. This was hardly an inspiring success story for imitation by others.

In Denmark, the government from 1979 combined an investment subsidy with the threat of regulation by law to induce utilities to conclude voluntary agreements with wind turbine owners – usually cooperatives – by which the latter would receive 85% of the consumer price for electricity and part of the connection costs. These agreements had to be renewed every few years. In the early 1990s, the utilities wanted lower payments per kilowatt hour and delayed a new agreement, whereupon the minister of energy in 1992 declared that the matter would henceforth be regulated by a law which maintained the 85% figure and which was passed by the alternative 'green' majority in parliament that existed alongside the government coalition. Within a few years this led to the biggest wind boom in Denmark involving several thousand cooperatives and some 100 000 owners; in addition, the Danish government asked utilities to develop wind farms on

their own. It also supported wind energy deployment via a state-financed quality program for turbines, rules for determining turbine locations etc. Parliament rejected nuclear power in 1985 and in 1990 made clear that no big coal plants would be permitted in the future, a step taken by few countries so far. In 2001, a new government stopped most support measures, but in the meantime Danish wind turbine makers were global leaders and leading exporters (van Est, 1999; Nielsen and Heymann, 2012; Hvelplund, 2005).

In Germany, market creation for renewables was first introduced by parliament against government and electricity incumbents. After Chernobyl, public opinion became solidly and permanently antinuclear. The Greens then committed to shut down nuclear plants should they come to power; the Social Democrats (also in opposition) to phasing them out gradually. Rising concerns over climate change led to a comprehensive consensus in parliament that market creation for renewables in the form of feed-in tariffs should be instituted. The Ministry of Economic Affairs – traditionally the patron of the electricity incumbents – opposed what it called 'perpetual subsidies.' Against strong resistance from their leadership, Conservative MPs in the late 1980s submitted members' bills requiring utilities to purchase and pay feed-in tariffs for all renewable electricity tendered to them by mostly small generators, at a rate of 90% of the consumer price (clearly inspired by Danish experience but not voluntary). The government reluctantly gave its consent since the cause was widely popular, elections were upcoming, and the incumbent utilities absorbed by taking over their East German counterparts during German reunification. Thus the Feed-in Law of 1990 was passed unanimously, although the utilities (and Conservative and Liberal leaders) viewed this as an accident in need of repair (Jacobsson and Lauber, 2006; Laird and Stefes, 2009). But for almost two decades these attempts at 'repair' remained without success, be it in the courts, parliament, or even EU institutions.

When in 1998 a Social Democratic-Green coalition replaced the Conservative-Liberal government, it started *Energiewende* or energy transition (i.e., to renewables and efficiency) by adopting the Renewable Energy Act of 2000 plus the phaseout of nuclear power against the preference of an Economic Affairs minister who would have preferred a quota/certificate system (see below) or even voluntary green tariffs. The philosophy of this act was to accelerate renewable power deployment by providing great security for investors in such technologies via an unlimited purchasing obligation of utilities for all renewable electricity, priority dispatch, and technologically differentiated, 'cost-covering' feed-in tariffs fixed for 20 years after installation and providing a modest return to installations properly built and managed. The extra cost of the tariffs would be borne by all electricity consumers via a surcharge, though exceptions were soon made for energy-intensive industries facing international competition. Cost and windfalls would be limited by taking account of size, quality of the site etc. Rapid and stable deployment should encourage mass production, technological learning, and price reductions even for technologies that were still expensive at the time the law was enacted, and also create new employment and exports. This investment in learning would be amortized by clean and cheap domestic electricity within a few decades and free Germany from import dependence (Jacobsson and Lauber, 2006; Mitchell et al., 2006; Hirschl, 2008).

This was a policy for the long haul and not dependent on the good will of utilities. Liberals and part of the Conservatives objected to the long suspension of 'market rules' (no competition between generators but 'only' between producers of turbines, solar cells etc.). Market creation was highly successful in terms of deployment. Onshore wind grew (cumulative capacity) from 55 MW in 1990 to 6.1000 MW in 2000 and 34.000 in 2013; PV from 2 MW (1990) and 114 MW (2000) to about 35.500 MW in 2013. In terms of electricity generation, the share of new renewables without hydro grew from near zero in 1990 to about 22% in 2013. Half of the investment came from about 1.5 million private persons. In 2010, the four big incumbents owned only about 6% of new renewables' capacity (trend:research, 2011). By that time, the renewable power sector had also created about 350 000 jobs.

Spain was the third European country to rapidly deploy wind and solar power, mostly by means of a market premium (fixed and technology specific, added to the electricity price). Mostly incumbent utilities profited from this highly lucrative system (given Spain's high level of electricity prices); rising demand meant that conventional generation was not threatened. For small generators a feed-in tariff offered lower but safer returns (Rio González, 2008).

An entirely different approach to market creation prevailed in the UK. Liberalization and privatization of electricity (Thatcher's reform projects) were meant to intensify competition and reduce prices. They also exposed that all nuclear power plants but one were making losses, not profits. Distributors were then required to carry a specific quota of (noncompetitive) nuclear power. This nuclear assistance program was baptized 'nonfossil fuel obligation (NFFO).' A creative bureaucrat decided that renewables were also 'nonfossil' and could thus bid for the quota. Bidding rounds were organized irregularly for renewable generators – originally financed by a fossil fuel levy – to make this a highly competitive process though almost meaningless in terms of renewable power installed. Intense competition for the windiest locations led to neglect of landscape considerations or local preferences and unleashed an aggressive antiwind power movement ('Country Guardians,' many of them friends of nuclear) even before a significant numbers of turbines were actually installed. It also brought down bid prices so far that many winning projects were never built. In 2002, the Blair government replaced NFFO by the Renewables Obligation (RO), based on similar economic philosophy to support only the currently cheapest sources to drive down their cost even further. The RO set an annual quota of renewable electricity (increasing over time) for all distributors, which they could meet from own generation or by buying RO certificates from others, or by paying a buyout price. Renewable generators receive the market price for electricity and the certificate price (plus some other elements). The system resembles emissions trading: volatile certificate prices, low security for investors, and thus need for high rates of return. This keeps out small generators, reserving a very lucrative business to utilities ambivalent about renewable power and helping them to keep transition to renewables under control by regularly under fulfilling the quota (Mitchell et al., 2006; Woodman and Mitchell, 2011).

A similar system was introduced in most U.S. states since the late 1990s: the renewable portfolio standard (quota). This quota system also favors the cheapest technologies (unless there is a set-aside e.g., for solar PV) and like the RO acts as a cap on deployment; if the quota is over fulfilled, certificate prices collapse (Lewis and Wiser, 2007). The resulting low security for investors and slow growth long prevented the rise of a renewables equipment industry in both the UK and the US. In the US, this was reinforced by the on–off character of federal tax credits for renewable power which led to huge swings in annual installations and long discouraged especially wind turbine producers from settling there.

When the European Commission tried to accelerate the internal market integration of the national renewable power sectors by legislation (renewable energy directives 2001/77/EC and 2009/28/EC), it argued that a quota system would be the most cost-efficient and also the most effective solution. Chief supporters of this move were Eurelectric (the association of European electricity incumbents) and the U.K. government. But in 2008, Commission staff submitted studies on the actual performance of the two support systems. They showed that quota systems generally paid the highest revenues and profits to renewable power generators and were the lowest on effective deployment. Feed-in tariffs combined high deployment with lower revenues and modest profits. On both occasions, Parliament and Council prevented the banning of feed-in tariffs pushed by the Commission (Lauber and Schenner, 2011).

In Japan, MITI launched an investment subsidy program for PV rooftops which made Japan the biggest PV market in the early 2000s but subsidies were reduced rather quickly, presumably due to the neoclassical aversion against supporting long-term learning investments and a clear preference for nuclear power as the mainstay of electricity supply (Chowdhury et al., 2014).

Theses examples show that market creation policies varied strongly with economic ideologies and the institutions that formulated those policies. Parliaments were decidedly more favorable to effective deployment often inspired by technological innovation system approaches (Jacobsson et al., 2009) while ministries and technocrats tended toward neoclassical restraint. Neoclassical quota systems such as RO and renewable portfolio standard (RPS) favored the cheapest renewable power technologies (often waste combustion and landfill gas), capped deployment at low levels, tended to produce large windfalls, profits for incumbents and contributed little to initially more expensive technologies such as solar PV, offshore wind etc. German-style feed-in tariffs supported wind, PV, and other sources simultaneously and without cap, and limited windfalls. Had the neoclassical approach prevailed – as favored in the late 1990s/early 2000s by the European Commission (and also IEA and the World Bank) – renewable energy development would not be nearly as advanced as it is now. PV would still be prohibitively expensive and wind energy less advanced. Under quota systems, growth of capital goods industries and technological learning concerning renewable power would have been much slower; up until about 2010 they were heavily concentrated in Denmark, Germany, and Spain. Electricity incumbents lukewarm about such technologies would still tell the story of high-priced renewables (in fact, 'noncompetitive' German feed-in tariffs for wind are lower than 'competitive' British RO payments despite the UK's better wind resources) and probably continue with fossil and nuclear for several more decades.

Global Surge of Photovoltaics Followed by Contraction in Europe

Between 2000 and 2010, wind power (worldwide) grew at an average annual rate of 27% (doubling every 4 years; see **Figure 1**); solar PV at a rate of 42% (doubling every 2 years; see **Figure 2**). Worldwide investment flows into the renewable electricity sector set new records every year. During this decade Europe was clearly leading the world in RES-E (renewable energy sources – electricity) development and deployment, with the US and China closing up. Some thought that the EU Emissions Trading System (EU ETS) would also promote renewable energy development, with rising carbon prices expected to reduce the role of coal. But until auctioning of certificates started in 2013, its perverse effects prevailed and ETS windfall profits for coal generators actually encouraged coal plants (Pahle et al., 2011).

In the mid-to-late 2000s, many European countries introduced a feed-in tariff for solar PV since quota systems – unless reformed by technological banding (successfully pushed in Britain by parliament) – failed to support this technology. PV's rapid deployment had unexpected effects. Economies of scale and technological learning made module prices fall faster than tariffs and stimulated demand even more; this resulted in speculative demand bubbles (and high legacy costs of tariffs). It also led to partial outsourcing of cell and module production to Southeast Asia. China's local and regional government levels supported the rise of a PV export industry with cheap land, low-cost long-term credit, and other privileges. Now subsidizing exports is outlawed by the World Trade Organization (WTO), but few European governments even tried invoking WTO rules to stem the onslaught of Chinese modules until the damage was largely done (i.e., by 2013). Many European governments compounded that damage by radical support cuts, sometimes even retroactive and particularly damaging to investor confidence, drastically reducing installations and driving many European cell and module producers into insolvency. China by contrast multiplied its domestic PV demand several times over to save its industry. The combined result of rapid technological learning plus trade war was that PV became reasonably cheap very quickly (cost reduction by about 80% in less than a decade) but was still perceived as expensive by many governments (due to its legacy costs, possibly also to intellectual inertia, and political opposition; see below).

The surge of PV had another effect explaining some of the slowness of many European governments to help this sector. It dealt a hard blow to incumbents relying on fossil and nuclear generation, biting into their profits and accelerating their decline. These incumbents now claimed the surge of renewables – particularly of PV – not only caused grid instability, the risk of blackouts, and energy poverty; worse, it threatened Europe's industry, employment, and global competitive position. Governments should therefore slow down this process in the public interest. This drama gathered intensity over the past few years.

The Impact of RES-E Deployment on Fossil and Nuclear Electricity Incumbents

Since the first half of the twentieth century, electricity incumbents – some of the most capital-intensive firms globally – developed a business model characterized by increasingly large-scale thermal technologies, highly centralized with a limited number of plants connected to urban and industrial consumption centers. This system grew along with electricity consumption. Until liberalization in the late twentieth century, it was largely protected against competition, by territorial monopolies whose regulation meant constant interaction with governments. Their corporate culture defined the right size of generation units in hundreds of MW to more than 1 GW; small units were a nostalgic utopia. With liberalization, substantial overcapacities emerged. The fact that new renewable energy technologies took off in parallel presented an additional challenge for the sector; it was natural that electricity incumbents would try to stop them or to subject them to their own system requirements (e.g., by a quota system).

Beginning in the mid-2000s the surge of renewable generation made itself felt in the countries leading on deployment. First, incumbents lost market shares, which diminished business volume but not infrastructure costs. Second, their most expensive generation plants were displaced by the merit-order system typical of liberalized markets under which generators are dispatched according to their marginal cost; this eliminated oil and then gas plants and reduced wholesale prices (and thus revenues) for all generation technologies. Third, they lost an increasing share of their most profitable generation – during the daily peak – to solar PV. These peaks now tended to become mid-day troughs in countries with large deployment of PV such as Germany and Italy (plus some neighbor countries sharing the same electricity exchange). Worse, PV deployment came with lightning speed when compared to the long gestation periods (10 years and more) for coal or nuclear plants – and some of these incumbents (e.g., in Germany) had built new coal plants with windfall profits from the EU ETS (Pahle, 2010), increasing surplus capacity. For many generators this meant heavy losses, poor credit ratings, and thus high costs of capital – and most of all, the perspective of further contraction and eventual demise. This fall from the throne came about within just a few years (Economist, 2013).

Political Efforts to Slow Down the Shift to Renewable Energy

This led to far-reaching political reactions. Politicians following neoclassical logic refurbished their old claim that RES-E support which ignored market competition was bound to lead to disaster and needed to be replaced with market-compatible instruments or scrapped entirely. They attacked feed-in tariffs, reduced them beyond plausible need or canceled them altogether. In Germany, the government in 2012 started to question the basic instrument of energy transition or Energiewende, i.e., the Renewable Energy Act, pointing to the apparently excessive cost of renewable electricity as reflected in the growing surcharge paid by consumers and burdening German industry. It called for capping RES-E growth and succeeded in changing the RES-E discourse even though its interpretation was singularly one-sided. It neglected that merit-order effects caused by renewable electricity had actually decreased wholesale electricity prices (which were benefiting half of industry but not passed on to household consumers and small industry by generators, distributors, or suppliers), and that half of industry was actually benefiting – not suffering – from the combination of lower wholesale prices with exemptions from the surcharge and grid fees.

In September 2013, nine of the biggest European utilities urged EU institutions to make sure that electricity prices reflect only market costs, not 'political measures.' This is directed particularly at market-creation policies which finance learning investments. They demanded that support for 'mature' RES-E technologies must be eliminated and restricted to R&D for infant technologies. By contrast conventional plants on standby for balancing fluctuating renewables should be supported by capacity payments. The emphasis in climate policy should be placed on emissions trading, a system that so far failed to produce the expected impact. By February 2014, the EU Commission supported the utilities' push in its proposals for nonbinding, low renewable energy targets for 2030, and for guidelines on state aid to renewable energy eliminating feed-in tariffs. On the national level, a similar policy approach has prevailed in some countries that formerly were leading RES-E development. Thus the German government is intent on putting the brakes on 'excessive' RES-E growth ever since 2010, despite Fukushima and subsequent talk of Energiewende. In Spain, successive governments dramatically reduced or eliminated premium payments for RES-E. In Italy, the government canceled a feed-in tariff that had led to the highest penetration of PV in Europe (7%), considerably higher than in Germany (5%). The U.K. government proposed to offer an incredibly lucrative feed-in tariff ('contract for difference') to a new nuclear plant but reduced plans for the use of abundant and cheaper wind power.

Renewable Electricity Development: Slower in Europe, on the Rise Globally

So in 2014 the world region which contributed the most to renewables development for about two decades – the European Union – is headed for a slowdown, with many of its leaders arguing that it cannot carry this burden alone. These arguments are put into practice just as RES-E development is bearing fruit in the form of lower prices, something that would call for an adjustment of policy but not for a change of goals. However, it is precisely this fruition which upset fossil electricity incumbents and motivated politicians to come to the rescue of this declining industry.

The US is in middle position. PV is finally taking off in the country that first massively invested in its development. However, many utilities fear that its most lucrative customers may become self-suppliers and look to displace or reduce net metering, or burden it with new fees; this conflict could yet hurt deployment. At the same time on–off tax credits and fracking constrain wind power development. Some utilities however are eager to capture – and if possible restrict – the solar PV rooftop business for themselves.

But this does not mean that RES-E deployment will slow down globally. In the early 2010s, leadership in production, diffusion, and increasingly technological development of renewable electricity shifted to China, which in 2013 was about at par with the EU in terms of RES-E installations but had much higher growth rates. Japan was suddenly propelled to a leading role in RES-E deployment due to a feed-in tariff voted after Fukushima. And while it was common to argue that only wealthy countries could afford wind turbines or PV, this has changed massively in recent years as the price for these devices has come down. The financial crisis dampened deployment particularly in Organisation for Economic Cooperation and Development (OECD) countries, but not so in others. Renewable electricity deployment is taking big steps in developing countries, with economics coming to its support. The virtual absence of a comprehensive grid in many of these countries encourages RES-E. Meteorological conditions and thus wind and solar resources are usually much more favorable than in Europe. The extraordinary capital cost of new coal and nuclear plants are a handicap, even for big utilities in wealthy countries. Furthermore, in 2013 the U.S. government, and later the World Bank, the European Investment Bank and the European Bank for Reconstruction of Development plus the U.K. government all pledged to no longer finance coal plants in developing countries except in very special situations. The import bill for fossil fuels is a heavy burden for many such states, and their prices are likely to go up over the long term. The price reductions for RES-E are creating new opportunities there. All across Asia, Latin America, and Africa numerous projects have sprung up in the current decade. Europe may take a back seat at its own risk; but it will not stop the rapid advance of RES-E technologies in the rest of the world.

Political Geography

Alexander B Murphy, University of Oregon, Eugene, OR, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Political geography is a subdiscipline of geography concerned with the spatial arrangement of political practices and understandings on Earth's surface, and the role of politics in shaping geographical patterns and processes. Political geography investigates why formalized political spaces develop, and how the configuration of those spaces reflects and shapes cultural, social, economic, and environmental circumstances. It also explores the geographical character of political and social movements, as well as the impacts of politics on the geographical organization of human activity and human–environment interactions. The academic study of geopolitics represents an additional important area of political-geographic inquiry.

Development of Modern Political Geography, 1890s–1970

The roots of political geography can be traced as far back as Aristotle's effort to describe the ideal state in terms of its territory, population, and internal geographical structure. The German geographer, Friedrich Ratzel (1844–1904), is often credited with being the progenitor of modern political geography. Ratzel argued that an understanding of the political world needed to be grounded in the human and physical character of the concrete territorial spaces occupied by states. He is most known for a Darwin-inspired 'organic theory,' which treated states as competitive territorial entities vying with one another for control over parts of Earth's surface. Ratzel's seminal book, *Politische Geographie* (1897), was the first major work to use the term political geography.

Ratzel's organic state theory attracted attention in both Europe and the United States. The Swedish political scientist, Rudolf Kjellén (1865–1922), drew on Ratzel's ideas to develop an elaborated vision of the state as an organism, in the process giving birth to the term 'geopolitics' (*see* Geopolitics). Contemporaneously, the American naval historian Alfred Thayer Mahan (1840–1914) published an influential set of works arguing that control over sea lanes and adjacent land areas was critical for the maintenance and expansion of political power. His work was soon followed by an alternative, more widely circulated geopolitical vision developed by the English geographer Sir Halford Mackinder (1861–1947). Mackinder emphasized the importance of the interior of the Eurasian landmass (the heartland) for the maintenance and spread of political power.

Given the relevance of these geopolitical contributions, and the interest they attracted, it is not surprising that the political geography of the early twentieth century was strongly identified with geostrategic thinking (Claval, 1994). Ratzel's and Kjellén's work became the foundation for a school of geopolitics (Geopolitik) in Germany led by Karl Haushofer (1869–1946), which eventually was appropriated by the Nazi war machine to justify its expansionist policies. In other parts of Europe and the United States, debates over the relative merits of Mahan's and Mackinder's conceptualizations attracted considerable attention in both academic and policy circles, and led to yet other geopolitical visions – most notably those of the Dutch-born, American-educated international relations scholar, Nicholas John Spykman (1893–1914), who focused attention on the strategic importance of the so-called rimland (coastal fringe) of Eurasia.

The first half of the twentieth century also saw political geographers being called upon to provide background on boundary disputes, internal divisions within empires, and the impacts of new transportation technologies on political areas. The director of the American Geographical Society, Isaiah Bowman (1878–1950), was a key advisor to President Wilson during and after World War I. Bowman was the chief territorial specialist of the American delegation to the Paris Peace Conference, where a new European political map was forged. In many cases, however, political compromises meant that Bowman's proposals for the redrawing of boundaries were not followed.

During the interwar period, the study of political geography expanded modestly in colleges and universities, although relatively few geographers defined themselves primarily as political geographers. Studies emphasized the historical territorial development and contemporary geographical characteristics of individual states. Bowman produced the first systematic political geography text of the post-World War I political order: *The New World: Problems in Political Geography* (1921). It concentrated on the territorial problems of the new countries of the world – particularly those in Europe. Richard Hartshorne (1899–1992) viewed this work as an extension of Ratzel's concern with the environmental character of state areas; Hartshorne's own influential work focused on the integrative (centrifugal) and disintegrative (centripetal) potentials of differing state territorial characteristics and founding territorial ideologies (summarized in Hartshorne, 1954).

The formal study of political geography declined during the middle decades of the twentieth century. Geopolitics in particular fell into wide disfavor during the middle of the twentieth century because of its association with Nazi efforts to justify claims to territory. In light of the close association between the study of geopolitics and of political geography, for decades after the war the Soviets opposed any use of the term political geography, and in Germany political geography ceased to be taught. Political geography maintained a foothold in the English-speaking academy, but its importance waned for a time. Nonetheless some efforts were made to examine new

geopolitical circumstances (Cohen, 1963), and to describe how geography affected individual states through the study of the spatial morphology, internal organization, locational characteristics, and boundaries of states (e.g., Prescott, 1965).

Political geography became somewhat disconnected from conceptual and empirical developments in other parts of geography when the discipline took a positivist turn during the late 1950s and 1960s. Partial exceptions could be found in studies of electoral patterns and political redistricting, which lent themselves to quantitative analysis. By the end of the 1960s, however, mainstream political geography was not a prominent subfield of geography.

Political Geography's Late-Twentieth-Century Revival

Political geography did not remain in a marginal position within the discipline of geography for long. An important edited compilation from the end of the 1960s (Kasperson and Minghi, 1969) provided a useful framework for teaching and research. Shortly thereafter, Jean Gottmann's (1973) study, *The Significance of Territory*, opened up new ways of thinking about the nature and meaning of the world political map. Moreover, 1970s-era scholars trained in urban and economic geography began to turn their attention to the role politics plays in the distribution of services, people, and wealth. The latter development spawned political-geographic work focused at local and regional scales. Notably, Kevin Cox's (1973) seminal book on the politics of urban services gave rise to an influential set of studies in 'welfare geography' that drew on Marxism and public choice theory.

Contemporaneously, expanded work on the spatial organization of elections, voting patterns, and the geography of representation made electoral geography an increasingly widely recognized subspecialty within political geography in the 1970s (Taylor and Johnston, 1979). Electoral geography widened the scope of political geography and attracted interest among a new generation of geographers. At the same time, the different scales and issues on which votes are taken encouraged a broadening of political geography's earlier preoccupation with the scale of the state.

By the early 1980s, the new work being undertaken on urban and electoral themes was attracting growing attention and helping to connect political geography to issues and concerns being taken up by other subdisciplines of geography and by the social sciences more generally. Moreover, traditional political-geographic themes were taking on new life, with expanding interest in shifting cold-war geopolitical relations, the growth of substate nationalist movements, and the emergence of new regimes of control in the world's oceans. The founding of a new journal, *Political Geography* (originally entitled *Political Geography Quarterly*), in 1982; the establishment of major research and study groups in the International Geographical Union and various national geographic organizations; and the founding of a boundary research institute at the University of Durham signaled the growing importance of the subdiscipline.

At the heart of political geography's revivification was a growth in interest in the role of politics in the larger discipline of geography and the effort by political geographers to develop a more sophisticated theoretical foundation for the subdiscipline. Impetus for the theoretical turn came from the combination of insights being offered by studies of urban social conflict from a political-economy perspective and an interest in making connections with work going on outside the subdiscipline. Explicit engagement with theory in political geography took four overlapping, sometimes conflicting forms: a concern with developing a theory of the state, a concern with understanding how systemic influences shape political-geographic processes, a concern with theorizing the human–territory relationship, and a concern with the role place plays in the development of political identities and practices.

The work of Gordon Clark and Michael Dear (1984) is particularly associated with the effort to theorize the state in political geography in the 1980s. Inspired by, but extending beyond, Marxian conceptions of the role states play in the maintenance and expansion of capitalism, Clark and Dear treated the state as a product of institutionalized political-economic patterns and associated spatial arrangements that influence how states develop. Their work helped to foster wide-ranging inquiries into the spatial dimensions of state policy initiatives, as well as studies of the 'local state' and its relationship to the national state. The latter was also heavily influenced by the writings of David Harvey (e.g., Harvey, 1985), who focused attention on how the capitalist accumulation process was linked to the political production of spatial inequalities within cities and substate regions.

The strand of work in political geography concerned with systemic influences focused particularly on the political-economic underpinnings of the state system and their role in shaping territorial practices and behaviors at the state and substate scales. British geographer Peter Taylor helped to advance this line of work – particularly through his influential text, *Political Geography: World-Economy, Nation-State and Locality* (Taylor, 1985 and later editions coauthored with Colin Flint). Drawing on the World Systems ideas of Immanuel Wallerstein, Taylor situated his analysis of the changing political geography of the modern world in the context of the territorial dynamics of the emerging capitalist world economy. He argued that the study of political-geographic processes at national and subnational scales could not be divorced from the positions states and local political units occupy in the global political-economic order.

Robert Sack's work on *Human Territoriality* (Sack, 1986) helped to catalyze a body of work that treated territory not simply as a framework for the projection of political power, but as a product of human ideas and behaviors. Sack argued that a critical component of human social behavior was the effort to influence people and ideas through the control of specific geographical areas, and that a concern with 'human territoriality' could therefore provide important insights into social and political processes. Sack's work directly challenged the dominant tendency to treat political territories as a priori spatial givens – in the process opening an important theoretical window for political-geographic work investigating how and why particular territorial arrangements come into being, and how those arrangements shape economic, social, cultural, and environmental processes (e.g., Murphy, 1996).

Work on the role place plays in the development of political identities and practices was spurred in particular by John

Agnew's (1987) influential volume *Place and Politics*. Agnew argued that political studies are generally based on the assumption that, in the modern world, local and regional identities are being replaced by national communities segmented by socioeconomic differences – not by geographic sectionalism. Agnew showed that this 'nationalization thesis' fails to account for the enduring impacts of local context on social and political behavior. Drawing on Italy as a case study, he demonstrated that political perspectives and identities were influenced not just by generalized economic circumstances but by local political culture. His work in this vein helped to foster a turn toward more localized studies in political geography.

The new theoretical perspectives coming into political geography during the 1980s influenced the types of issues being studied and how they were studied. The relationship between political geography and uneven development became a particularly significant focus of attention (see Smith, 1984). Political geographers also turned their attention to processes of nation-building and substate nationalism, seeing these as predicated in significant part on the territorial dynamics of the state system. Studies in electoral geography also began to look at the relationship between spatial structures of power and electoral outcomes.

Work on the politics of place and on territoriality developed in conjunction with the late-twentieth-century turn toward post-structuralist approaches in human geography – in the process helping to open up new vistas for political geography. The centrality of politics and political relations to post-structuralist thought greatly abetted this process (Painter, 1995). The academic study of geopolitics was particularly influenced by the post-structuralist turn, giving rise to a body of work known as critical geopolitics. Influenced by Foucauldian ideas, the critical geopolitics literature looks at the discourse of geopolitical practice to gain insight into the ways in which spatial understandings have been developed, deployed, and manipulated in the pursuit of political and military objectives (see Ó Tuathail, 1996). Foucauldian perspectives also promoted new relational approaches to territory, which cast territory not simply as the historical outcome of struggles for control over Earth's surface, but as the outcome of a set of relationships linking individuals and groups with the material and discursive environments in which they are situated (see, e.g., Raffestin, 1980; Storey, 2001).

Contemporary Approaches and Themes

Much of human geography as currently practiced is about politics – making it difficult to establish exactly what distinguishes political geography from other branches of human geography. Yet as Agnew (1997: 3) has argued, "there is nevertheless still the need for an area of study of the more formalized and institutionalized arenas of power such as the spatiality of states, interstate geopolitics, the geographies of political and social movements, and territorial conflicts involving national and ethnic groups." These are the matters that continue to be most closely associated with the subdiscipline of political geography, and they are not particularly confining. Indeed, the contemporary political geography literature addresses themes that range from the ways in which gendered identities undergird particular political-geographic practices to the implications of new telecommunications technologies for the territorial integrity of states.

Much of the recent work in political geography is rooted in approaches that are traceable to three intellectual currents that have shaped the subdiscipline over time: (1) political geography's tradition of describing and analyzing the spatial configuration, geographic character, and boundaries of politically organized areas; (2) the political-economy perspectives on political-territorial developments that began to influence the subdiscipline in the 1970s and 1980s; and (3) the more recent cultural turn that reflects growing interest in the insights that post-structuralist theories of society can provide on the spatial dimensions of political processes. Some studies can still be neatly classified in one or another of these analytical traditions, but there is also considerable blurring among them. Nevertheless, tensions persist among proponents of these different perspectives, the most acute of which is between those who posit a world of 'real' political spaces/arrangements that we can comprehend through some combination of empirical and critical analysis, and those who view reality as unknowable outside of the individuals and societies that construct it.

The substantive topics on which contemporary political geographers are working are a product of the more general effort to make sense of the rapidly changing political, social, and economic environment of recent decades. The following subsections highlight a number of key areas of concern. There is considerable overlap among and between these areas of research, but each has a core literature attached to it.

Political-Geographic Assumptions of Social and Political Theory

There is a pervasive tendency in the social sciences to frame analyses of social and political developments in terms of the political territories in which they are situated. Yet the territories themselves are usually treated as little more than locational referents for whatever is being studied. A body of work in political geography seeks to expose the shortcomings of this way of thinking. Much of that work focuses particularly on the importance of understanding what is hidden and what is revealed when the modern territorial state is treated as an unproblematic spatial container for social and political processes. John Agnew in particular has argued that this approach is the product of a cognitive 'territorial trap' that leads scholars and other commentators to ignore critical historical and geographical processes (see Agnew, 1994). In support of this line of reasoning, a number of political-geographic studies have shown how the political organization of space is itself implicated in social and political processes – even shaping the very concepts of identity on which political communities are based. The nature and meaning of territory has also come under increased scrutiny, most notably in the form of a major treatise tracing the historical development of the concept in the Western tradition (Elden, 2013).

Geopolitical Conceptualizations and Practice

Geopolitics is clearly back on the political geography agenda, as evidenced by the interest in critical geopolitics, by the publication of a spate of recent books, and by the founding of

a journal titled *Geopolitics* in 1996 (its name for the first 2 years was *Geopolitics and International Boundaries*). The recent literature on the subject reveals some continuing interest in the development of formal geopolitical models, but recent studies in this vein have concentrated on the changing geopolitical environment for interstate relations and on the worldviews and priorities of political actors. Considerable attention has been paid to the emergence of the modern world economy and its impacts on the conceptualization and pursuit of geopolitics. Feminist perspectives on geopolitics have also shaped the subdiscipline in recent years (Hyndman, 2003) – encouraging consideration of the ways in which gendered identities and power relations affect geopolitical conceptions and practices. Political geographers with an interest in geopolitics have also examined topics as diverse as the locational components of conflict, the geopolitical dimensions of environmental change, and the ways in which popular culture reflects and shapes geopolitical practice. The end of the Cold War and the initiation of a US-led 'War on Terror' represent a particularly important empirical focus of investigation, with studies examining the ways in which geopolitical ideas and practices are influenced by the inertia of colonial relationships and by the understandings of territory and terror that developed in conjunction with the modern state system (Gregory, 2004; Flint, 2005; Elden, 2009).

Deterritorialization, Reterritorialization, and the Changing Nature of Sovereignty

There is a lively debate in political geography and beyond about the degree to which the traditional role of the state is being undermined by the increased mobility of capital and labor, the growing power of multinational corporations, the advent of new transportation and communications technologies that decrease or eliminate the friction of distance, and the rise of extrastate trading blocs and political organizations (see generally Agnew, 2009; Murphy, 2013). This debate finds concrete expression in studies focused on the ways in which these developments are fostering either deterritorialization and a concomitant undermining of traditional sovereignty arrangements, or reterritorialization and a reassertion of traditional state sovereignty. In an effort to unravel the complexities of the shifting political-territorial order, political geographers are raising questions about the changing nature and function of boundaries; the distribution of powers among and between substate, state, and superstate political-territorial entities; and the means by which governments at different scales are seeking to integrate and defend their territories. Such efforts have led political geographers to focus growing attention on political spaces above and below the scale of the state, as well as to study new political spaces of cooperation along international boundaries and geographically distant political communities that are forging links outside the framework of states.

The Rescaling of Political Practice

Closely related to the prior theme is a concern with the ways in which the scale of political practice is changing. The Keynesian welfare state of the early to mid-twentieth century reinforced the importance of the state scale in the development and implementation of economic and social policy. Over the past few decades, however, changes in the dominant modes of economic production and capital accumulation have worked together with intensified globalization to produce a global shift toward neoliberal political-economic arrangements. Many traditional state practices have been pushed downward to the substate level, whereas others have been taken up by supranational entities and institutions. The extent and political-geographic implications of this rescaling of political power have emerged as a significant theme in political geography – bringing political geographers into conversation with social and economic theorists interested in the changing nature of governance. The geographical dynamics of multilevel governance have attracted particular attention, as has urban government, which has often had to bear the brunt of the abdication of traditional state responsibilities in the social and economic arenas (e.g., Brenner, 2004). At even smaller spatial scales, there is a growing body of political-geographic work focused on political practice in the home, schools, and other microscale settings. Informed by feminist scholarship, studies in this vein have examined, for example, on the impacts of neoliberal political-economic arrangements on 'private' spaces (see, e.g., England, 2003).

Boundaries, Identity, and Citizenship

Political geographers have long been interested in the ways in which the political organization of space reflects and shapes patterns of identity – emphasizing, for example, the often discordant relationship between the map of nations, in the original sense of the term (a group of people sharing a common sense of cultural and political identity), and the map of states. The rise of so many visible instances of ethnonational conflict over the past few decades has moved the relationship between political territoriality and identity to the center of the political geography agenda. Political-geographic research has focused on the competing territorial ideologies and strategies of majority and minority groups, the ways in which the political organization of territory affects intergroup interaction and intragroup identity, and the structures and arrangements that lead to the reproduction of state nationalism. The infusion of post-structuralist ideas into political geography has also promoted interest in the ways in which governmentality (in the Foucauldian sense) and the practices of everyday life influence the nature and meaning of citizenship in an increasingly mobile world (see Painter, 2006; Staeheli et al., 2012), as well as the meanings that are ascribed to particular territories and nationalized landscapes. Indeed, there is growing recognition that how political spaces are understood or imagined can, in many instances, be more socially and politically influential than how they are actually configured (see, e.g., Sidaway, 2002).

The Political Geography of the Environment

One of the clearest obstacles to the effort to confront environmental problems is the fragmentation of the planet into

political spaces, few of which are meaningful ecological units. The issue is not just that ecological and political boundaries do not coincide; the very roles that territorial states play in the international state system and the world economy frequently work against collective action in the interests of the environment (Johnston, 1996). Building on a tradition of examining the relationship between spaces of governance and environmental geographies, political geographers are increasingly turning their attention to environmental questions. Recent work has focused on new transnational regulation regimes and the special issues presented by environments that do not lie within the territories of individual states: the world's oceans and Antarctica. Political geographers have also focused considerable attention on questions of environmental security and the geopolitical implications of environmental change (e.g., Dalby, 2009). At smaller scales, political geographers have examined the circumstances giving rise to the emergence of environmental movements in particular places, the problems and prospects of collective resource management in different political contexts, and the use of environmental strategies in the pursuit of political-territorial objectives. Some of this work is closely aligned with the emerging field of political ecology, with its focus on the role of political-economic arrangements in the production of local environmental outcomes.

Political Movements

Studies in electoral geography have long focused on the spatial dynamics of a particular type of political movements that seek to influence formal elections. Political geographers continue to study electoral patterns – influenced increasingly by structuralist and post-structuralist theorizations of space, place, and power (Warf and Lieb, 2011). With new political movements increasingly challenging long-standing political arrangements, a variety of other types of political movements are commanding attention as well. Work in political geography has focused on the political-territorial contexts that give rise to such movements, the spatial character of movement support, and the impacts of movement objectives on the political organization of space. A significant body of recent literature focuses on political movements that have coalesced around such social categories as race, gender, sexual identity, and ethnicity. Political geographers have also explored the geographical foundations and consequences of antistate movements and other forms of resistance that seek to counter dominant the political-economic structures and arrangements (see, e.g., Pickerill and Chatterton, 2006) – a scholarly endeavor that traces its lineage to Peter Kropotkin's famous 1885 essay, 'What Geography Should Be.' The concept of place – as politically and socially constructed – is central to much of the work on political movements because places provide the foundations for the development of such movements and because identification with place often shapes social and political identities. A considerable body of scholarship focuses on the ways in which dominant interests create spaces or places of marginalization that reflect and reinforce existing power relations and social prejudices.

The Way Forward

Political geography has emerged as one of the most vibrant and active areas of inquiry within the discipline of geography, and it is likely to remain so since the political-territorial upheavals of recent years show no signs of abating. Interest in political geography will likely be fueled by growing challenges to the role of the state – challenges that will further undermine the long-standing tendency throughout the social sciences to treat states simply as taken-for-granted spaces in which social processes play out. Rapid changes in the spatial organization of politics will also likely foster growing efforts to comprehend the nature and meaning of the changing political-territorial order. Studies in political geography will likely continue to be interdisciplinary in character, while underscoring the idea that political practices and outcomes cannot be divorced from the changing geographical spaces and contexts within which they are situated.

Abstract

The first and still one of the greatest political histories ever written is Thucydides's *Peloponnesian War*, in which we find many of the themes that continue to fascinate students of politics. I shall begin by examining the development of international political history from Thucydides to the present. Another important subject of political history, also with classical roots, is the development of law and institutions. Here I will be especially concerned with the significance of legal history for the development of modern historiography. In the nineteenth century, political history became closely associated with the nation-state, whose story was at once the record and instrument of nationbuilding. But while political history is often allied with established authority, it can also become a weapon of political dissent by providing an alternative narrative to aspiring political parties, social movements, and subject nationalities. For most of the history of historiography, political history dominated the discipline. Beginning in the 1960s, however, first in the United States and then in Western Europe, traditional political history came under attack, first by social, then by cultural historians. After considering the character of the ensuing debate, I will conclude with some tentative thoughts about the role of political history in the future.

Political history is the study of how legitimate power has been defined, distributed, and justified in the past (*see* Power). Two imperatives, both with ancient roots, link historiography and politics. The first is the need to affirm the identity of the political community by uncovering its roots in the past. This search for historical identity engaged both the Hebrews and Greeks at the very beginning of European culture; it moved the Romans to search for the sources of their state and prompted succeeding generations to study the history of their cultures, religions, and nations. "No question," wrote Jean Bodin in the sixteenth century, "has exercised the writers of histories more than the origin of peoples" (Kelley, 1998). The second link between history and politics is the desire to find lessons in the past that might help solve the political problems of the present. "I shall be content," Thucydides remarked in the first chapter of *The Peloponnesian War*, "if (this history) be judged useful by those inquirers who desire an exact knowledge of the past as an aid to the understanding of the future" (Thucydides, 1996).

From the Ancient World to the End of the Middle Ages

Political history in the West begins with two masterpieces: Herodotus's history of the Persian Wars, written between 445 and 425 BC and Thucydides's history of the long conflict between Athens and Sparta, which he began in 424 BC and left unfinished when he died a quarter of a century later. Products of the extraordinary burst of cultural energy that transformed fifth- and fourth-century BC Greece, Herodotus and Thucydides combined a deep sense of the importance of their own age – Herodotus wrote about the recent past, Thucydides about events in which he himself had taken part – with an awareness of the historian's responsibility to establish the truth about the past. Both men reflected on the problems of historical research, the reliability of eye witnesses, and the necessity of critically analyzing source material. More than any particular way of writing history, this was their most significant legacy for future historians (*see* Historical Thought and Historiography: Classical Period (Especially Greece and Rome)).

The study of history was more important in Rome than it had been in Greece, perhaps because Romans were always conscious of their complex historical relationship to the Greek culture that they had both vanquished and absorbed. Roman historians examined the problem of politics from a variety of perspectives; they wrote about leadership and institutions, military strategy and court intrigue, republican virtues, and imperial ambitions. But behind these disparate approaches was a common theme: the origins, triumph, and – eventually – the decline of the Roman state, which, as republic and empire, dominated the public life of the Mediterranean world for 700 years and then continued to haunt Europeans' historical imagination until well into the nineteenth century.

The emergence of Christianity and its adoption as the Roman Empire's official religion transformed all of Western culture, including both politics and history. Christianity's most immediate contribution to political historiography was to pose the problem of church and state, which would decisively shape the theory and practice of European politics from the end of the Roman Empire to the beginning of the twentieth century. Unlike the pagans whom they displaced or the Hebrew traditions upon which they built, Christians created religious institutions that were connected to, but not coincident with, the sources of political authority. "Spiritual and secular power," Ranke (1962) wrote, "could approach one another and be intimately related, but they could be fused only under exceptional circumstances and for a brief period of time. Their relationships and conflicts provide one of history's most important themes." From Eusebius's history of the church, which reflected the triumph of Constantine's conversion at the beginning of the fourth century, to Otto of Freising's twelfth-century chronicle, *The Two Cities*, which described the conflict between empire and papacy, to Ranke's own history of the popes, which bore the marks of nineteenth-century's struggles

between church and state, historians searched the past for clues to the proper relationship between God and Caesar, pope and emperor, altar and throne, religious autonomy and secular authority (*see* Historiography and Historical Thought: Christian Tradition).

History and the State

Beginning in the 1490s with the French invasion of the Italian Peninsula, a series of international, constitutional, and religious crises disrupted European politics and helped to create a new subject for political history. This subject was, in Quentin Skinner's (1978) concise summary, "the concept of the state – its nature, its powers, its right to common obedience." The concept of the state emerged from the dissolution of two closely connected assumptions that had shaped European political thought since Augustine: first, that the secular realm of politics had to be seen as part of a sacred order; and second, that Europe's components – its free cities, ecclesiastical states, and various monarchies – were part of a single polity, governed by the universal laws of the church and sustained by the institutional legacies of imperial Rome. A good deal of medieval political theory and practice had been devoted to reconciling these assumptions with the stubborn realities of political life; in the first decades of the sixteenth century, Europeans began groping their way toward new ways of thinking about politics – and, therefore, toward a new kind of political history.

One of the first signs of this can be found in the work of Niccoló Machiavelli. As a Florentine who had been forced into exile by the collapse of his city's constitutional order, Machiavelli felt the political crisis of the early sixteenth century at first hand. In *The Prince and The History of Florence*, Machiavelli sketched a political world that Thucydides would have recognized immediately, a world driven by struggles for power, beset by violence, subject to forces that are often beyond human capacities to control. A similar picture emerges in the work of Machiavelli's fellow citizen and contemporary, Francesco Guicciardini, whose histories provide an even darker picture of instability and violence. But however limited people's ability to control events, history, for both Machiavelli and Guicciardini, was a totally human enterprise, untouched by the hand of God, unfettered by a transcendent order.

Machiavelli wrote about 'the state,' but without giving it a clear institutional definition. This would be the great achievement of sixteenth- and seventeenth-century legal humanists, whose study of the law provided a new foundation for both politics and history. Of course law had always been an important part of European culture, but scholars like Guillaume Budé, Jean Bodin, François Baudouin, and François Hotman combined philological methods and historical analysis to create a new science of jurisprudence that enabled them to establish the origins, nature, and limits of the state's authority. Bodin, for example, provided the classic definition of sovereignty as the supreme source of law within a commonwealth, exercised by, but clearly independent from, the ruler's person. The work of these scholars stands at the source of one of political history's richest traditions: the study of legal institutions and constitutional development, which includes among its practitioners such giants as Montesquieu, Sauvigny, and Maine (Kelley, 1970).

Law was also important to those who sought a vision of the international order to replace medieval universalism. Hugo Grotius, for example, who wrote during the Thirty Years War in the first half of the seventeenth century, argued that the international order was based on natural laws, which were divinely ordained but could be discovered by examining the past; like the French legal humanists, Grotius regarded the study of law and history as part of a single enterprise. By the end of the eighteenth century, under the influence of a new set of crises generated by the French Revolution (*see* French Revolution, The) and Napoleonic conquests, a number of scholars searched for an international system that was no longer based on God-given laws but was still subject to underlying principles that the historian could discover. Heeren (1834), for instance, wrote that the 'essential property' of the European state system was its "internal freedom, that is, the stability and mutual independence of its members. To set forth how this was formed, endangered, and preserved…is the great object of the historian."

The historical image of a world of independent states struggling for existence within an international system was given its definitive formulation in the middle decades of the nineteenth century by Leopold von Ranke, perhaps the greatest political historian of the modern era (*see* Historiography and Historical Thought: Modern History in the West since the Eighteenth Century). Von Ranke is best known for his archival work and his insistence on the critical use of primary sources. But inseparable from Ranke the great empiricist was Ranke the moral philosopher of statehood, who regarded states as the 'ideas of God' that move through the historical order 'like celestial bodies.' His work, which combined scholarly rigor with stylistic grace, was read widely and admired throughout Europe; his methods of teaching and research were adopted everywhere (see Krieger, 1977).

History and the Nation

Of all kinds of history, the history of the nation has the deepest roots and the most widely extended branches (*see* Nation: Sociological Aspects of). Its first and most persistently influential expression was in the Hebrew Bible, which recounts the archetypical story of a nation's origins, defines its special historical mission, traces its survival in the face of terrible trials, and promises its eventual triumph. Their story, the Hebrews' historians insisted, is a story like no other – among the many ways in which national histories resemble one another, none is more striking than their insistence on being unique. As for so many other nations without states, this national history sustained the Jewish people's sense of collective identity through centuries of dispersal and oppression. And once the Jewish nation finally had its state, the story of the national past became – and this is also characteristic of the genre – the site of political debates about the nation's present identity and future direction (*see* Historical Thought and Historiography: Jewish Tradition).

Although national history has a genealogy that extends to the dawn of Western culture, its most intellectually vigorous and politically potent versions were written in the nineteenth century when, for the first time, political history became virtually synonymous with the history of nations and nation-states (*see* State, History of). The nineteenth century was, of course, the great age of historical writing, a time when historical consciousness touched virtually every aspect of European culture, from art and literature to philosophy and the social thought and even the natural sciences. For most nineteenth-century intellectuals, to think about the world was to think about historical origins, evolution, and identity. This was a time when statesmen – men like Guizot and Macaulay – wrote history and when historians – Bancroft, Droysen, Treitschke – were active in political affairs. And this was also the era when the institutional foundation for modern historical scholarship – document collections, libraries and archives, journals and reference works – was created, much of it by, and often for, national governments (*see* Historicism).

While every nation has a story to tell about itself, every national story is different, shaped by the political imperatives, cultural climate, and institutional arrangements of each national community. Nineteenth-century French historians, for instance, whose state had an unusually long and apparently uninterrupted existence, were able to imagine a single national history. Their problem was how to find a place in this history for the trauma of revolutionary upheavals and prolonged warfare that engulfed France after 1789. For almost two centuries, French historiography was shaped by political struggles over the revolution's legacy, just as French politics was influenced by historical struggles about the revolution's character and significance. Among the works engaged by this project are such classics of political historiography as Tocqueville's *Ancien Regime and the French Revolution* and Michelet's *History of the French Revolution* (*see* Tocqueville, Alexis de (1805–59)). It was not until the 1970s that François Furet could declare that the French Revolution was finally over, by which he meant that it had lost its central place in the nation's political discourse and public memory.

Each national experience poses a distinctive ensemble of questions for its historians to confront. In Britain, these are most often questions about institutional continuity rather than revolutionary ruptures. In the US, the central historical issue is the question of identity itself, which was addressed in works like Frederick Jackson Turner's classic study of the frontier in American history (*see* Frontiers in History). The problem of identity also dominated German historiography in the nineteenth century: before the creation of a German nation-state, this meant a competition between different versions of the national past, after national unification, it involved demonstrating that the nation created by Bismarckian 'blood and iron' was the only authentic destination for the German people's long historical journey toward political unity. In the twentieth century, German history was shaped by efforts to locate the catastrophe of National Socialism in the national past: was National Socialism, as some claimed, the destination of Germany's 'special path' (*Sonderweg*) to modernization, or was it a particularly toxic example of a broader crisis within modern culture and politics (*see* National Socialism and Fascism)?

An important element in the public life of every nineteenth-century state, history was even more significant for those national communities that did not have a state of their own. For the Poles, the Irish, the Czechs, and, in the course of the twentieth century, for the peoples of the world colonized by Europeans, a shared history was the surest source of present cohesion and the brightest hope for future nationhood. After all, what else did these nations possess besides their belief in a common ancestry? Often enough, this belief had to be constructed from the scattered remnants of an imagined past – literary works discovered and transcribed by patriotic scholars, ancient sites unearthed by archaeologists, memories of lost greatness brought to life in poems and plays and popular histories. Often enough the character of the national past was bitterly contested – by Czechs and Germans in Bohemia, Protestants and Catholics in Ireland, conservatives and liberals in partitioned Poland, Muslims and Christians in the Balkans. In these parts of the world, the historical significance of John Hus, whether the town was called Derry or Londonderry, the meaning of the Polish uprising of 1863, or how to commemorate the battle of Kosovo could swiftly become matters of life or death. Every national history reflects ideological divisions and political conflict, but in nations without states, the seam between politics and history was nearly invisible, so that it was usually impossible to determine where the one began and other ended.

Subversive Histories

Although historians have often been the servants of those in power, there is also a long, rich tradition of subversive historiography, written by scholars who turned to the past in order to question the established order and suggest new paths for the future. In the nineteenth century, at the same time that historians were drawn into the service of the nation-state, subversive historiography was given its most influential formulation by Karl Marx. For him, the political movements that had interested Thucydides, Machiavelli, and Ranke are surface phenomena, reflections of the deeper social conflicts from which history takes its shape and direction. Politics is merely an instrument of the ruling class, a way of justifying and defending its hold on the means of production. Traditional political historians, therefore, view the past through a distorting lens that turns the world upside down, obscuring the essential sources of change with their concern for artificial conflicts, empty slogans, and trivial events. The Marxist historian's purpose is to substitute for these ideological distortions the radical clarity of scientific materialism, which will reveal to the proletariat the roots of its oppression and thus help prepare them for their revolutionary role in history cosmic drama. From the last decades of the nineteenth century until the end of the twentieth, Marxism – in all its many forms – remained the most influential form of subversive historiography (*see* Marx, Karl (1818–83); Field Theory).

Well before the final collapse of international communism in 1989, Marxist historiography had begun to lose its intellectual attraction and political influence. In part this was because of the diminution of ideological energies both in the communist regimes of Eastern Europe and in labor movements

throughout the world. Moreover, by the 1970s, the political passions that had drawn intellectuals to Marxism during the struggle against fascism in the 1930s and against colonialism in the 1960s had cooled. The Marxist view of history was also undermined by a growing skepticism about all grand narratives, a turning away from the aspiration to grasp the meaning of human history as a whole. And finally, Marxism declined because it could not explain very well the subjects to which more and more historians now turned, especially problems of ethnicity, race, and gender, which did not fit into the categories defined by the means of production. Not surprisingly, the form of Marxism that remained most influential in Britain, the US, and most of Western Europe was associated with historians like E.P. Thompson, who tried – not always with success – to fuse class analysis with a concern for culture and politics (*see* Social History).

Since the decline of Marxism, the subversive impulse in historiography has been fed from many other sources of which the most important, at least in the last two decades of the twentieth century, was certainly the work of the French philosopher and historian, Michel Foucault (*see* Boserup, Ester (1910–99)). Like Marx, Foucault's enemies were oppression and inequality, his goals, freedom and community. But unlike Marx, he did not propose an alternative view of history or a critical science of society. Foucault's project was willfully fragmented; he called his approach to the past a genealogy rather than a narrative history. Deeply concerned about what he regarded as the repressive power of organized knowledge, he was nevertheless unwilling to abandon efforts to understand and subvert the existing order of things. Above all, this meant to understand and subvert power, which was exercised not only by the agents of the state but rather was diffused "in the multiple forms of subjugation that have a place and function within the social organism." Emancipation, therefore, required a struggle against all of what Foucault regarded as the "polymorphous techniques of subjugation" (Dirks et al., 1994).

Marx (and also, if much less influentially, Freud) had sought to subvert traditional political history by showing that politics was really a reflection of deeper social (or psychological) conflicts (*see* Psychohistory). Foucault subverted the conventional image of politics from the opposite direction, that is, not by showing that politics should be reduced to something else, but rather by insisting that everything – including what was once thought of as the most intimate spheres of private life – is politically charged. Both perspectives are useful since both can illuminate new problems and neglected connections. Whether they can – and should – lead to the abandonment of the subjects that have concerned political historians since classical times is much more open to question.

The Varieties of Political History in the Twentieth Century

Scholars' interest in the past has always been influenced by contemporary crises. Thucydides was moved to write his history by the Athenians' disastrous war with Sparta, Josephus recorded the destruction of the Jewish people by the Romans, and Augustine composed his universal history under the shadow of the Vandals' sacking of Rome. In the modern era, the French Revolution inspired Tocqueville, the Bolshevik Revolution, Trotsky, the rise of Italian Fascism, Salvemini, Nazi totalitarianism, Arendt, the World Wars, Churchill – the list might easily be extended to include many other occasions when, to borrow Hegel's phrase, men's hopes were destroyed on history's slaughter bench.

The War that shattered the world order in 1914 dominated the study of international political history for a quarter of a century (*see* First World War, The). Basing their work on the documents published by all of the belligerents, historians examined both the immediate causes of the war and its deeper roots in the great power rivalries of the nineteenth century. Some of this work was obviously partisan, written to absolve the historian's own nation of responsibility; but much of it sought to strike a balance between commitment and detachment. A notable feature of this historiography was the participation of American scholars. Responding to the hopes and disappointments that attended the failure of Woodrow Wilson's vision of a conciliatory peace, these scholars – Sidney Fay, Robert Binkley, William L. Langer, Raymond J. Sontag, and many others – played an active role in controversy over the causes and consequences of the war. By the 1930s, there was a rough scholarly consensus that no one power was responsible for the war, which was thought to have come from a series of miscalculations by several different governments. In the 1960s, this consensus was shattered by the work of Fritz Fischer and his students who attempted to blame the war on Germany's reckless bid for world power. Fischer's view was bitterly attacked and then widely accepted, but no new consensus has emerged to explain what George Kennan, himself a distinguished student of international history, once called "the great seminal catastrophe of the century" (Stevenson, 1997).

In contrast to World War I, the causes of World War II did not attract much scholarly attention; virtually everyone agreed that this was Hitler's war (*see* Second World War, The). But the war's character and consequences generated an enormous historical literature, including some great works by participants such as Winston Churchill and Charles DeGaulle. Historical controversies surrounded issues such as the air war (especially the decision to use atomic weapons against Japan), wartime diplomacy, and the role of resistance and collaboration in the territories occupied by Germany and Japan. Among the historical questions about the war in Europe none are more painfully complex than those surrounding the mass murder of European Jews, conventionally known as the Holocaust. Was it, as some scholars believe, tied to a distinctive sort of German anti-Semitism? Or did it arise within the climate of violence created by the war itself? Is it best seen as a problem of German history? Or of modernity as a whole? Could it have been prevented or at least diminished by the action of Germany's enemies? Central to the historical self-understanding of both perpetrators and victims, the Holocaust has become the century's exemplary disaster (Marrus, 1987) (*see* Holocaust, The).

The origins of the Cold War, the global geopolitical rivalry between the Soviet Union and the US that dominated international politics from 1945 to 1989, were a matter of intense scholarly controversy throughout its long history. Was the Cold War, as some claimed, a defensive response by the Western powers to communist aggression and expansionism?

Or, as the so-called 'revisionists' argued, did the US over estimate, perhaps even manufacture, the communist threat in order to advance its own aims throughout the world? Until the collapse of the Soviet Union, both sides in this controversy depended largely upon sources from the Western powers, but after 1989, the empirical basis of Cold War historiography was transformed by the opening of archives in both the former Soviet Union and its Eastern European allies. As a result, historians have begun to create a new picture of international history in the second half of the twentieth century (Gaddis, 1997).

Among the great themes of world history is the expansion of European power which began in the late fifteenth century and ended during the second half of the twentieth century, when the colonial states either abandoned or were expelled from their overseas possessions (*see* Imperialism, History of). European expansion was the subject of many important historical studies, including the analyses by J.A. Hobson and V.I. Lenin that inspired several generations of anti-imperialist writers. Decolonization also had a lively historiography, stimulated in part by the traumatic wars fought by France in Algeria and by the US in Indochina. In the 1990s, historians became interested in what became known as postcolonialism, that is, the persistent and reciprocal relationship between colonized and colonizer both during and after the colonial experience itself. While many postcolonial studies take up issues that seem far distant from conventional political history – for instance, questions of gender, sexuality, and cultural identity – they are all connected to the ways in which political power is defined and distributed.

In the last decades of the twentieth century, political historians have become increasing aware of the importance of regional and loyal allegiances and institutions. A number of recent works on the revolutions of 1848, such as Jonathan Sperber's account of the Rhineland, have shown how tensions between central and local authorities affected both the origins and outcome of the revolution. Historians have also become sensitive to the historicity of the national state: Eugen Weber, for instance, has described the long and uneven process through which the French state imposed its values in the countryside, while Linda Colley, among many others, has uncovered the way in which Britain became a focus of people's interests and loyalties. The upheavals that destroyed Yugoslavia in the 1990s produced a cluster of new works on the historical sources of ethnic identity and changing nature of nationalism in the twentieth century (*see* Nationalism: General; Nationalism, Historical Aspects of: The West). In these studies, traditional questions about state power and politics are enriched by a new concern for ethnicity, culture, and identity.

Conclusion: Political History in the Twenty-First Century

Although it no longer has the unquestioned historiographical primacy it once enjoyed, the history of politics remains a vigorous and remarkably diverse enterprise. For the general public, political history is a source of apparently endless fascination. Each year a staggering number of books, especially biographies and battle narratives, are published about subjects such as the American Civil War and World War II. Among professional historians there are signs that political history may have recovered some of the ground lost to social and cultural history in the 1970s and 1980s. An increasing number of scholars are now seeking to apply social scientific methods and concepts to the study of both domestic and international politics (*see* History and the Social Sciences). At the same time, insights from cultural anthropology (*see* Anthropology and History) and literary criticism have raised interesting new questions about the nature of political power and identity.

The history of politics is important because individuals' lives are shaped and limited by political institutions, while the very existence of their communities depends on how political power is exercised and restrained. The illusion that politics does not matter is a luxury that only those fortunate enough to live in a rich and orderly state can afford. Moreover, while the importance of national history may have declined in Western Europe, for much of humanity the question of national identity remains vitally relevant; in many places people are still willing to die – and to kill – in behalf of their own version of the national story. And the emergence of a new set of problems and opportunities from the wreckage of the Cold War system (*see* Cold War, The) will certainly raise a new set of questions about the past and future of the international politics.

Does knowledge of the past help us, as Thucydides and Machiavelli and so many others believed, to master our own political problems? To be sure, few now share the confidence expressed by Lord Acton in his inaugural lecture of 1895 that "the science of politics is the one science that is deposited by the streams of history, like the grains of gold in the sand of a river; and the knowledge of the past, the record of truths revealed by experience, is eminently practical, as an instrument of action and a power that goes to making the future" (Acton, 1957, pp. 25, 26). And yet the impulse to extract lessons from the past seems irresistible; historical references and analogies are everywhere a prominent part of political discourse. If nothing else, the study of past politics should help to assay the ore left by the stream of history and to recognize the fool's gold so often on display in the rhetoric of public life.

Political Lawyering

Abstract

Political lawyering refers to a mode of lawyers' collective politics in struggles over the rise and fall of political liberalism. Extensive historical and comparative research demonstrates that lawyers, in certain circumstances, will fight for a moderate state, civil society, and basic legal freedoms. Those struggles always occur through the politics of a legal complex of all legally trained occupations continuing to act in a legal capacity. Configurations of the legal complex frequently ally with civil society groups, including the media, justice-related associations, and religious organizations. Consequently, transitions from authoritarian and illiberal regimes to liberal political societies, including postcolonial societies, frequently are spearheaded by political lawyers in coalitions with elements of the legal complex and civil society. This approach to studying the politics of lawyers is contrasted with the study of cause lawyering and of lawyers' role in transforming state power.

Scholarship on the comparative and historical politics of lawyers took a significant turn in the late 1990s. In previous decades, two sharply contrasting approaches to lawyers' politics had been observed.

At the height of functionalist theory, which dominated the theory of professions during the years 1950–70, politics was essentially absent from studies on the link between knowledge and social needs. Society delegated to a community of professionals a set of duties, undergirded by 'institutionalized altruism,' and rewarded professionals highly for their fiduciary contributions to society. Neither politics nor collective action, nor historical or comparative analysis, were needed to explain the integrative functions of lawyers.

A sharp critique of functionalism then emerged from a sociology that was deeply skeptical about lawyers' professional ideologies and practices of 'service' and civic-mindedness. Magali Sarfatti Larson's (Larson, 1977) highly generative book, *The Rise of Professionalism*, presented a counternarrative to functionalist accounts that managed to neglect class, conflict, and occupational self-interest. Lawyers, and other professionals, had engaged historically in collective action for a double purpose: collective upward mobility in the class system and creation of professional services as a commodity. From this nuanced and sophisticated analysis was derived a theory of market control whereby the politics of lawyers became a mechanism of rent seeking. Lawyers mobilized, argued Abel and Lewis (Abel and Lewis, 1988a,b) and many of their collaborators, to monopolize markets and maximize profits. Collective action was largely taken for granted and mobilization for reasons other than economic interests entirely neglected.

Even the paradigmatically ecological theory of professions presented by Abbott (Abbott, 1988), which offered acute insights into ways that professions mobilize knowledge in their scramble for control over work, did not treat either the political processes by which professions secure and maintain jurisdictional control, or the activities of professions beyond control of work domains.

In the 1990s, several strands of scholarship on the politics of lawyers emerged. New line of historical and comparative scholarship emerged to critique the limitations of a market-oriented lawyers' politics and to explore theoretically and empirically the engagement of lawyers in the politics of political liberalism, state building, and cause advocacy. This article encapsulates the broad contours of lawyers' collective politics in struggles over the rise and fall of political liberalism, a mode of action labeled 'political lawyering.' The article concludes with brief contrasts between political lawyering and alternative formulations of lawyers' political activity that also emerged in the 1990s, which emphasizes lawyers as utility maximizers or as cause lawyers.

Political Lawyering

Extensive historical and comparative research cumulatively has demonstrated that fights for political liberalism have been integral to the politics of lawyers and to the politics of states in a wide variety of times and places (Halliday and Karpik, 1997; Halliday et al., 2007a, 2013). These politics, while diverse and variegated, nevertheless frequently register a coherence that can be bundled within the concept of political liberalism.

Political Liberalism

For lawyers, political liberalism has three principal components:

1. A moderate state, which fragments political power into constitutionally structured contestation among elements of the state, including legislatures, executive agencies, and courts. For lawyers, the most critical element of the moderate state is a degree of autonomy of the judiciary from other branches of government.
2. Civil society, which is constituted as social organization that exists substantially independent of the state. Civil society expresses itself in two forms. It is a web of associations that fills a middle ground between the state and tribe or family. It does not owe its existence to the state and can stand against it. Associational life is expressed empirically in voluntary groups, religious organizations, unions,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86092-4

interest groups, women's associations, among others. Civil society constitutes a public sphere where opinions are freely expressed, ideas circulate, and politics becomes informed by discursive encounters (Habermas, 1989). For lawyers, their associations both constitute civil society and look to civil society for political allies and supportive publics in struggles for political liberalism.

3. Basic legal freedoms, which comprise three parts. First, there are core legal rights to protect citizens from arbitrary state power (e.g., rights to due process in law, habeas corpus, right to a lawyer, freedom from arbitrary arrest, torture, death). Second, there are basic political rights of freedom of speech, association, and movement, all of which are foundational for the existence of civil society. Third, there are property rights, which offer protections for citizens against arbitrary appropriation of land or other property by the state or others.

Three important qualifications must immediately be noted. First, there is nothing inevitable or invariant about lawyers' mobilization for political liberalism. Because lawyers frequently do *not* mobilize on behalf of these three features of political liberalism, this is a contingent theory that requires attention to the conditions under which mobilization occurs. Second, when lawyers do mobilize collectively most often it is around this tight set of goals. Like other citizens, lawyers divide on many substantive political issues, but even deeply divided legal professions can find common ground on the core attributes of political liberalism. That implies the use of ideal types. Third, lawyers historically have not mobilized as a whole for economic and social freedoms. The political liberalism of lawyers is limited.

In sum, wide-ranging interdisciplinary research across the world and on the last 300 years to the present shows that a political commonality can frequently be found in lawyers' readiness to mobilize collectively to build political liberalism or to fight against retreats from a moderate state, the dismantling of civil society, the control of the public sphere, or erosions of basic legal freedoms.

Five Propositions

In European and North American history, the political activism of the legal profession as a periodic but by no means consistent mode of action could be expressed in five propositions:

1. The autonomy of the judiciary and the autonomy of the bar are the principal conditions for the fight of lawyers on behalf of a moderate state. Unless the courts have some measure of independence from executive power, or judges are prepared to fight for autonomy from political control, then effective mobilization will be unlikely. And unless the bar itself has a degree of independence from executive or other state control, then its collective action will be impaired or impossible. It is not surprising, therefore, that struggles for judicial autonomy by the French *parlements* in eighteenth-century France (Karpik, 2000), or periodic defenses of the English bar to maintain their independence as 'little republics' in the English body politics, or contemporary struggles by a vanguard of lawyers in China, have resonances in common.
2. Historically, lawyers' collective defense of civil rights did not extend to economic and social rights. Most often lawyers' collective action has been possible only for core civil rights, not for second or third generation rights, such as universal education, social welfare, universal voting rights, and the like. Rarely did lawyers as a whole mobilize again racism, or xenophobia, or gender discrimination.
3. Lawyers most often act reactively, not proactively. That is, they were provoked into action by arbitrary or illegal actions by governments. Sometimes mobilization coalesces around *causes célèbres*, mostly notably, widely publicized court trials. They frequently have sought solidarity and support from publics and civil society.
4. Courts can become the central locus of battles on behalf of liberal political society. Courts have three benefits for lawyers' politics: they are often protected spaces, allowing speech and opinions that would not be permitted elsewhere; they are lawyers' battleground of choice, since they operate by a *legal* rather than a political logic, and thus give lawyers a technical advantage; and they are the arena into which society's most vexing disputes about state power eventually can appear (Karpik, 2007).
5. Lawyers have generic capacities to act as spokespersons for publics. Insofar as lawyers are occupationally charged with representation of others, they frequently parlay that individual lawyer–client role into a collective lawyer–society role where they may claim to speak to power on behalf of publics and civil society in favor of political liberalism (Karpik, 2007).

The Legal Complex and Political Liberalism

As research findings accumulated from Latin America, Africa, and Asia, it became clear that a politics of lawyers alone was inadequate as an explanatory theory of mobilization on behalf of political liberalism. Almost always lawyers' mobilization was intricately intertwined not only with the actions of judges but with other legally trained occupations. These findings led to the naming of a new collective actor – the legal complex (Karpik and Halliday, 2011).

The Legal Complex Is Defined by Five General Characteristics

1. It is composed, in principle, of *all legally trained occupations* that are continuing to act in a legal capacity. It includes practicing private lawyers, who usually form the core of the legal complex; legal academics; judges; prosecutors; law officials inside government; and lawyers in the military. In some countries, it includes grassroot lawyers who offer legal advice or lawyers whose licenses have been withdrawn for political reasons.
2. It is defined behaviorally in terms of *current actions*, not past training. It excludes persons exclusively trained as lawyers, but who later become government officials, business persons, nonprofit leaders, politicians, and are not acting in legal roles in those positions.
3. It is a concept intended to capture *collective action*. That is, the legal complex putatively acts across the conventional divides that segregate academic research on courts and judges from those on private lawyers from those on prosecutors.

4. It expresses itself in varieties of *structures*. Research on the legal complex requires attention to the structures that enable or preclude mobilization across conventional cleavages among categories of legally trained professions. For instance, in relations between lawyers and judges within the legal complex, analysis will attend to relations that are cooperative, or oppositional, or detached, or crosscutting, or multiplex. Each kind of relationship and each structural property may have explanatory significance for capacities to mobilize. In other words, the diversity of the interdependency in relations among groups is expressed by different structures and by different types and degree of mobilization.
5. It is highly *dynamic*. Not only may the legal complex mobilize in very different ways on different issues, but the legal complex may be differentially constituted and structured in different places and times across different aspects of political liberalism.

Dynamics of the Legal Complex toward Political Liberalism

Research on several continents in the twentieth century shows that mobilization by the legal complex has occurred in at least four patterns (Halliday et al., 2007b). These show the flexibility of the concept for social science and historical analysis and the contingency of actions by the legal complex, which require further specification in the development of theory on political lawyering and political liberalism.

1. There are many instances where the legal complex in several of its components – lawyers and judges, sometimes with academics and prosecutors, or with civil servants or military lawyers – has acted on behalf of basic legal freedoms. In several countries, this has led to relatively robust liberal political societies. Mobilization by many lawyers, then judges, prosecutors, and legal academics was integral to dramatic regime transformation in South Korea and Taiwan as military dictatorships yielded slowly to constitutional political orders. In other countries, such as Egypt in the 1990s, or Venezuela in the 1980s and 1990s, mobilization by a vanguard of lawyers before sympathetic courts led to short-lived legal and political openings, which eventually resulted in political or military backlash (Moustafa, 2007). Even in colonial Hong Kong, some government lawyers found common cause with barristers to defend basic rights.
2. There are occasions when lawyers mobilize without the support of judges and therefore may be compelled to rely more on legal academics or find support outside the legal complex in civil society. In Japan from 1886 to the1920s and after the 1980s, lawyers pressed for politically liberal reforms, even for a more active and autonomous judiciary, but they did so in the face of judicial passivity. In China since the early 2000s, a vanguard of lawyers has sought to mobilize the bar as a whole, with some support from the legal academy, to protect basic legal freedoms, but it has confronted an 'iron triangle' of judges, police, and prosecutors who have resisted. After 9/11 in the United States, many private lawyers, some bar associations, and even military lawyers sought greater protection for detainees, but judges were slow to permit those protections.
3. In some situations, a legal profession and judiciary, which previously has fought for political liberalism instead fails to mobilize. Two cases illustrate where selective mobilization can occur, both focused on security. In one set of cases, mobilization fails in response to *external* threats to security. In Israel, an otherwise vocal legal complex remained silent about certain illiberal policies of Israel's state and courts. In the U.S., the fear of terrorism, which followed 9/11, temporarily silenced otherwise activist lawyer groups. In another set of cases, rampant criminality *internal* to a country, such as Argentina and Brazil in the 1990s, led government prosecutors and judges to withhold action against police brutality and killings of suspects (Brinks, 2008).
4. There are many instances where all or most of the legal complex were hostile to defense of basic legal freedoms. Research shows that lawyers and judges in 1930s Weimar Germany, lawyers in 1920s Fascist Italy, lawyers and judges in militarizing Japan in the 1930s, lawyers confronted with Pinochet's State of Siege in 1970s Chile, among others, could not or did not stand collectively or in force against dictatorial regimes.

Political Liberalism in the Postcolony

While much research showed evidences of political lawyering in widely diverse polities across time and place, it did not confront one of the most fundamental transformations in twentieth-century politics – the fall of the European colonial empires. Since British imperialism at once held in tension the contradictory actions of illiberal conquest with tempered liberal ideals of rule of law, it became an empirical and theoretical challenge to discover whether political lawyering extended to resistance to illiberal colonial politics and to construction of postcolonial liberal polities.

Postcolonial histories and world histories have yet to study extensively the politics of lawyers and the legal complex in the postcolony. Halliday et al. (2013) build upon interdisciplinary scholarship on South Asia, South East Asia, and Africa to propose that postindependence countries exemplified three political trajectories. The role of the legal complex varied systematically across these trajectories.

A *liberal-legal* political order emerges and is sustained in countries such as India and Namibia. Despite their differences and deviations, these countries historically have shared extension in practice of basic legal rights, including core political rights, for their citizens; place legal restraints on state power; limit recourse to use of emergency powers; and permit growth of civil society and an open public sphere.

A *despotic* political order, observed in states as diverse as Sudan, Singapore, and Sri Lanka, severely limits exercise of core political rights, minimizes restraints on executive powers by judiciaries, relies extensively on emergency powers for the security apparatus, and offers little protection of basic legal freedoms to those deemed political opponents of an authoritarian or totalitarian state.

A *volatile* political order, evident in Malaysia, Pakistan, Zambia, and Malawi, lurches back and forth historically in its movements sometimes toward political liberalism and

sometimes toward despotism but never institutionalizes either of these. These almost cyclical histories are distinctive in themselves because they persist over decades.

Research and theory is underdeveloped on the extent of legal complex involvement in these respective trajectories, but some preliminary conclusions have been proposed.

It appears that the probability of a postcolonial polity that is politically liberal increases (1) if the legal complex already had been fighting for independence during the colonial period; (2) if divisions of race, language, and religion are transcended in microcosm within the legal complex by common commitment to liberal legalism; (3) if the legal complex has found allies in civil society; and (4) if a national legal complex can draw upon an international legal complex for resources and support.

The probability of a postcolonial polity becoming a despotic order appears higher when (1) a colonial bar or bench has been passive in its relations with the colonial regime, (2) when politically active lawyers are targeted for repression by a state and bar associations are controlled or silenced by the regime, (3) when courts are packed with politically subservient judges, (4) when the legal complex is so divided by race or class or religion that it cannot mobilize as a collective legal actor, and (5) when states repress associations and voices in civil society that are potential allies for a politically liberal-legal complex.

A volatile political order appears to be associated with an unstable legal complex where: (1) the bar retains a memory or has a vision of a liberal-legal political order, but is too weak or divided to fight for it; (2) there is a judiciary that follows political currents rather than has some autonomy from politics; and (3) there exists a civil society that also expands and contracts as political freedoms open or close.

International Contexts for Political Lawyering

During the heyday of the British Empire, the seeds of political liberalism were scattered across the world alongside a coercive colonial apparatus that those seeds would eventually dislodge. Following World War II, the breakup of the European empires, and a resurgence of globalization and law, political lawyering in most countries could not be entirely localized, even by authoritarian regimes. Although research remains limited, fragments of evidence show that international influences often matter and matter a great deal. They may flow across borders in the form of ideas, as in the influences of Continental European thinkers on judges in Franco's Spain. They may be facilitated by close ties built on security relationships, such as the impact of the U.S. rights ideas on Korean and Taiwanese political lawyers in the liberalization that gathered momentum in the 1980s. They include the influences of international bar associations and legal NGOs, which may monitor countries, issue reports, and attempt to shame repressive governments. They stem from global norms promulgated by the U.N. or human rights or rule of law organizations. They can be tangible, in flows of money and advice, as was the case in Egypt in the 1990s and early 2000s. They are magnified by the international media, as contemporary worldwide coverage of China's human rights abuses frequently feature political lawyers.

These studies point to attributes of states and civil society before and after independence that interact with the properties of the legal complex to more or less facilitative of political lawyering. The variety and complexity of these remain understudied, especially as they vary across empires.

Political Lawyering and Civil Society

Repeatedly, in metropolitan, colonial, postcolonial, and other societies, the interplay between political lawyering and civil society constitutes a key part of the history and theory of political liberalism. In general it can be concluded that the availability of civil society associations as political partners for the legal complex depend upon: (1) whether associational life is viable; (2) what ideological orientations are adopted by associations, most importantly, whether they engage 'political' issues; (3) which leaders and resources are available to social groups outside the state; and (4) whether voluntary associations are prepared to join alliances or even be led by the legal complex.

Four types of civil society groups recur in lawyers' politics:

1. Justice-related associations may be most proximate to the legal complex and therefore are frequent political allies or even prompts for the legal complex. These include human rights groups, monitors of police behavior or judicial decisions, drafters of manifestoes for legal/political change, critics of the justice system, and defenders of prisoners. Frequently they are led or heavily populated by lawyers.
2. The media offer much to political lawyers and the legal complex but the media also have an ambivalent position in struggles for political liberalism. On the one hand, there are many instances (e.g., Spain, Egypt, Brazil, India, Malaysia) where the old media have reported mobilization by lawyers and judges, published op-eds by legal academics, publicized abuses of rights, shown corruption in the courts, among others. On the other hand, the media frequently are targets of state control (e.g., Singapore, Venezuela) or are restrained by market pressures precisely because they threaten the authoritarian rule directly or in alliance with the legal complex (Rajah, 2012). A significant new development for many legal professions (e.g., China) has been the explosion of new media, which allow instant reports, graphic images, and exchanges between political lawyers and publics, in some cases producing instant public action.
3. Religious groups also have an ambivalent relationship with political liberalism. While earlier histories (Bell, 1994) found common cause between a 'Protestant-like' strand of eighteenth-century Catholicism and struggles by lawyers and judges for liberal politics, there is much evidence of Christian groups, which have resisted political liberalism. Numerous twentieth-century examples can be found of religious groups mobilizing with the legal complex, including fragments of the Roman Catholic Church in Franco's Spain, Pinochet's Chile, Brazil's Dirty War, Lee Kuan Yew's Singapore, and Zambia's resistance to emergence of a Big Man regime. Protestants in Kenya, Zambia, and South Korea and prominent leaders within

the legal complex itself, such as China's *weiquan* lawyers, similarly have mobilized. Too little is yet known about other world religions, such as Buddhism, Islam, and Taoism. Not enough attention has been paid to whatever affinities there might explain the resilience of liberal politics in India and its predominant Hindu religion. Yet there are many instances where religion has been complicit, or indifferent, or silent, or divided in the face of political repression, including repression against lawyers. A contingent theory of religion and political lawyering remains to be developed, especially given religious resurgence across the world in recent years.

4. Political parties, too, can support or subvert political liberalism. One-party states by definition remain largely resistant to political liberalism since the essence of the moderate state is the checking of state powers controlled by a single party. But multiparty politics can also subvert the legal complex if and when the politics within the legal complex are not a politics of legalism but an internalization of statewide party contests. In this latter case the legal complex is riven with party conflict and the prospect of transcending party politics to find a common ground of legalism (e.g., defense of basic legal freedoms) dims or fades away completely. This has been an enduring problem in Latin American tensions between political liberalism and democracy (Hilbink, 2007).
5. In some African countries, the national grassroots influence of women's groups has been an aid to political lawyering for liberal politics. Trade unions, if independent and if not deliberately crushed or controlled, also offer an organizational ally for activist bar associations.

Nevertheless, as Karpik demonstrated for eighteenth-century France, political mobilization can be spearheaded by lawyers acting as spokesmen for publics (Karpik, 2000). Notable instances in Pakistan and Malaysia since the 1990s demonstrate that this can occur collectively, when the bar as a whole takes to the streets and has its voice magnified by old and new media. Yet individual notables in the legal complex – a chief judge, a leading barrister, a law dean – can also purport to speak on behalf of publics as if they had been appointed spokespersons. In these senses, the public square can be infused with debate led by notables in the legal complex or even by lawyers in the new media whom authoritarian governments would prefer to render invisible.

Alternative Approaches to Lawyers and Politics

Political lawyering as a distinctive approach to understanding lawyers' politics, which emphasizes their collective action through the legal complex for the goal of political liberalism is compared with two other approaches to the analysis of lawyers' politics.

Cause Lawyering

A substantial body of scholarship accumulated in the 1990s and 2000s on cause lawyering. Scheingold and Sarat, the leaders of this scholarly movement, stated, "cause lawyering is about using legal skills to pursue ends and ideals that transcend client service" (Scheingold and Sarat, 2004: 3). Unlike the classic image of the lawyer as a 'hired gun,' exercising zealous advocacy and technical expertise irrespective of the merits of a client's case or its moral implications, the common element of cause lawyering is that the lawyer mobilizes the law on behalf of clients whose moral and political ideals they share. By mobilizing the arsenal of legal weapons on behalf of their own ideals, cause lawyers meld their personal beliefs with their legal work on behalf of clients who share their values. Nevertheless, Scheingold and Sarat argued, a single, cross-cultural and historically valid definition that would encompass all cause lawyering was not possible.

The range of causes supported by cause lawyers can be enormously variegated, ranging from pay equity, animal rights, capital punishment, Bedouin land rights, struggles against military repression and capital punishment, fighting for women's rights, peasant movements, and human rights (see case studies in Sarat and Scheingold, 1998, 2001, 2006). In their definitive summing up of 15 years of cause lawyering writing and research, Scheingold and Sarat show how the concept became increasingly expansive over time. Although initially focused on causes associated with the liberal left in the U.S. and elsewhere, the definition came to embrace lawyering on behalf of causes associated with the political right as those activities expanded, including antiabortion, libertarian resistance to state regulation of the environment, and property rights.

Cause lawyering is a form of doing politics (Scheingold and Sarat, 2004). Politics comes in two guises in this literature.

On the one hand there are *political ends*. Thus "cause lawyering is first and foremost a creature of and contributor to liberal democracy" (Scheingold and Sarat, 2004: 122). Yet, cause lawyering can also embrace ideals that may be antithetical to liberal democracy, such as three movements they label as evangelical advocacy, social democratic, and emancipatory democratic politics (Scheingold and Sarat, 2004: ch. 5). In principle, it appears, lawyers' causes could extend to defense of illiberal politics and authoritarian states. That is, the definition of 'cause' is now emptied of any particular political content.

On the other hand there are *political means*. Cause lawyers may mobilize through the law itself, utilizing its weapons and waging their campaigns in courts and other legal arenas. Cause lawyers may also mobilize outside the law, using conventional political strategies, such as aligning with social movements, adopting tactics of insurgent politics, and the like.

The evolving and expanding concept of cause lawyering converges at some points with the core of political lawyering, insofar as Scheingold and Sarat argued that all cause lawyers, at least in the U.S., concurred on a commitment to first generation or basic legal rights, such *as habeas corpus* (2004: 132). Both political and cause lawyers are activists. Beyond those points, however, Karpik (2007) shows there are fundamental differences in these forms of political activism.

First, political lawyers are focused on a tight core of goals potentially common to all in the legal complex, whereas cause lawyers traverse a limitless range of moral and political ideals that divide the legal complex. Political lawyering reaches historically to the collective identity of the bar and the fight for

and defense of basic legal freedoms that are integral to that identity, Cause lawyers, say Scheingold and Sarat (2004: 6), "put themselves ethically at odds with the vast majority of lawyers."

Second, political lawyering has a long history, emerging over several hundred years, whereas most cause lawyering treated in recent scholarship has flourished in recent decades, initially in developed countries, later in developing countries.

Third, since political lawyering centers on an age-old struggle between states and civil society over core freedoms, political lawyers benefit from long historical precedent that 'to defend individual rights has become self-evident.' Cause lawyers cannot take for granted that an issue will be considered a 'cause' and therefore must justify their mobilization without precedent to draw upon.

Fourth, their long history has endowed political lawyers with the resources of "a voluminous political philosophy, a repertoire of forms of action and a privileged position within the liberal state." Cause lawyers by contrast and by definition more often have limited symbolic, technical and financial resources, especially for new causes, where justifications and resources must be built from the ground up.

In summary, says Karpik (2007: 492):

> Political lawyers and cause lawyers do not share the same issues, the same history, the same references and they share only partly the repertoire of forms of action. They do not occupy the same position in the bar; they do not receive the same solidarity. Their relationships with history, with political philosophy, with the state, with civil society are different.

Lawyers in the Field of State Power

Another sustained line of writings on the politics of lawyers has concentrated on their involvement in the transformations of state power, mostly in the development contexts of Latin America and Asia. Led by Yves Dezalay and Bryant Garth (Dezalay and Garth, 2002, 2010), this approach has a continuity with political and cause lawyering of a focus on lawyers as political actors, and an apparent continuity with aspects of political lawyering insofar as lawyers strive for rule of law or restructuring the state by promoting more powerful and independent judiciaries.

Nevertheless, sharp discontinuities distinguish it from other approaches.

First, this approach is state-centered. It concerns itself with the ways power is structured by the state and exercised by the state, whether in colonial or postcolonial situations. Thus, Dezalay and Garth show how the British colonial power in India invested in law and courts whereas in Indonesia there was limited investment in law by the Dutch, who were mostly content to rely on local law for governance. This approach does not concern itself with the constitution of civil society nor the representation of marginal individuals most vulnerable to assaults on their basic legal freedoms or personal vulnerabilities.

Second, this is a politics of elite lawyers in contrast both to cause lawyers, who are more often marginal, and to political lawyers, who range from professional elites to ordinary practitioners. It does not refer to the bar as a whole, nor acknowledge any core identity common to the bar, nor attend significantly to collective action by the bar.

Third, these lawyers engaged in the field of state power mobilize not on behalf of legal, moral, or political ideals about a good society or good polity, but to maximize their own 'professional rewards' (Dezalay and Garth, 2010: 10–11). They do not act for their clients or the bar writ large but for their personal career ambitions. A kind of legal opportunism is juxtaposed with occasional 'legal idealism' (Dezalay and Garth, 2010: 60) but for the most part these lawyers are characterized as capital-accumulating utility optimizers. Underlying this orientation to lawyers' politics is an implicit motivational theory, derived from Bourdieu, on lawyers' accumulation of various sorts of capital – social capital, 'legal capital,' 'family and state capital' (Dezalay and Garth, 2010: 3). These lawyers are economistic rational actors variously 'investing' in 'capital' and 'profiting' from returns on investment.

Fourth, if earlier investments yield later rewards, then attention to lawyers' careers becomes a paramount analytic strategy. These elite lawyers are constantly mobile as their portfolio of capital expands and diversifies. At one moment they may invest in trade and commerce, in another in human rights, in another in governance. For example, U.S. lawyers who affected the field of state power in the Philippines simultaneously invested in commerce but redeemed it by also investing in foreign policy, the state and international relations (Dezalay and Garth, 2010: 52). Indeed, it is a strength of this approach that it does not draw a sharp dichotomy between those lawyers who practice in the market and those who enter politics. One may enable the other and indeed many legal elites move back and forth between them. Paradoxically this point of view repeats aspects of the theory of market control that has been subjected to sustained critique.

In contrast to the tone of the political lawyering and cause lawyering approaches, which accept that lawyers may be driven by ideals beyond self-gratification, the state power approach offers a skeptical theory of lawyers' politics. Speaking on behalf of publics or civil society, for instance, is less a means of fighting for basic legal freedoms than a source of prestige or a means of accumulating political capital (Dezalay and Garth, 2010: 26ff).

In sum, the lawyers-and-state orientation involves legal elites exercising power. These elites mobilize individual resources accumulated as an aggregation of 'capitals' during their careers. While they are situated in social structures high in the prestige hierarchies of professional work, they tend to represent or depend upon the collective mobilization of the bar as a whole. Unlike the political lawyering and cause lawyering perspectives, they evince no coherent or consistent set of values that would alter the structure of state power in one way or another. Nevertheless, their individual impacts may be substantial in the field of state power.

Conclusion

Lawyers' politics have emerged as a significant site of theory and research since the 1990s. Those politics are salient to a wide range of scholarly and pragmatic issues, ranging from comparative politics, postcolonialism, economic

development and citizenship to constitutionalism, human rights, rule of law, and state structures.

Political lawyering expresses a form of lawyers' politics, embedded in a wider legal complex, that have deep historical provenances, strong philosophical foundations, and variegated comparative expressions. Insofar as political lawyering is integral to the viability of liberal polities, arguably a necessary condition of democracy, foundational for constitutionalism and rule law, and demonstrably an incipient danger to authoritarian rulers, military dictatorships, one-party politics, and Big Man regimes, then it must be the case that the extension of empirical research in varieties of settings and the refinement of contingent theories of mobilization for basic legal freedoms is an imperative for scholarly inquiry.

Political Money and Party Finance

Abstract

Healthy democratic politics depends on a free flow of information among citizens, groups, candidates for public office, and political parties. The right to speak diminishes in significance without the ability to be heard, and that speech is often conditional on the availability of financial resources to pay for public communication. Yet the manner in which political money is raised and spent can undermine the legitimacy of democratic politics. Efforts to prevent concentrations of wealth from undermining political equality or introducing corruption may conflict with bedrock freedoms of speech and association. Every democracy struggles to reconcile the need for political money with the problems it begets. None have found entirely satisfactory and long-lasting solutions. The political finance tools available to policy makers – public subsidies for candidates and political parties, limits and controls on political contributions and expenditures, disclosure requirements, and regulation of campaign activity – often leave reformers unsatisfied and produce unanticipated consequences. Not all political finance measures are doomed to fail, nor are they miracle cures for the ills arising from money in politics. Democracies will continue to struggle not to solve these problems once and for all, but to contain and manage them as best as they can.

Healthy democratic politics depends on a free flow of information among citizens, groups, candidates for public office, and political parties. The right to speak diminishes in significance without the ability to be heard. In the legendary words of California Assembly Speaker Jesse Unruh, "Money is the mother's milk of politics." Yet the manner in which political money is raised and spent can undermine the legitimacy of democratic politics and effective governance. Ensuring that parties and candidates have adequate resources to compete effectively in elections is problematic, given the inevitable tension between the reality of economic inequality and the ideal of political equality. Efforts to prevent concentrations of wealth from undermining political equality or introducing corruption may conflict with bedrock freedoms of speech and association. Every democracy struggles to reconcile the need for political money with the problems it begets, ranging from classic *quid-pro-quo* corruption or extortion to the perception or reality of undue access to or influence over policy makers and government decisions. None have found entirely satisfactory and long-lasting solutions. The political finance tools available to policy makers – public subsidies for candidates and political parties, limits and controls on political contributions and expenditures, disclosure requirements, and regulation of campaign activity – often leave reformers with unfulfilled objectives and unanticipated consequences.

Institutional Context

The prominence and nature of money in politics vary across institutional settings. Party-centered electoral systems differ substantially from candidate-centered systems. In the former, most often associated with the parliamentary systems of Western Europe, political money means party finance. Most, if not all, political funds are raised and spent by political parties, and the primary concerns have to do with the adequacy of funds available for routine party activities, the work of party caucuses in parliament, and election campaigns. Direct and indirect public subsidies are often provided to the parties, including cash and free broadcasting time on state-owned networks. There is substantial variation in the extent of regulation of party finance, with disclosure of large private contributions and prohibitions on paid political advertising the most typical, and limits on the size of contributions the least typical. Party-centered systems have not been immune from escalating campaign costs and scandals, as the clean hands investigation in Italy, the 'illegal earnings scandal' involving Helmut Kohl's Christian Democrats in Germany in the late 1990s, and the more recent charges involving former French President Nicolas Sarkozy illustrate. But the problems associated with political money in party-centered systems are relatively contained and finance practices are generally viewed as in need of monitoring and repair, not radical surgery.

In candidate-centered systems, by contrast, the focus is less on political party activity and more on campaign fund-raising and spending by individual candidates. In these systems, the term of choice is campaign finance rather than party finance. The United States is, of course, the most prominent example of this class of democracies and the most atypical one in its various components. While parties once dominated the recruitment of candidates and the waging of campaigns in the United States, a host of developments, including the creation of a professional civil service, the spread of the direct primary, the rise of television and other paid media, the reform of party rules, and the provision of substantial staff resources to public officials, diminished their role. Party organizations in the United States became largely appendages of incumbent officeholders – more instruments for raising money within and beyond the constraints of the law, rather than independent political actors. The recent increase in partisan polarization in the United States has given parties and their networks of activists and organizations a more important role in campaign finance but candidates remain the dominant players. Political money in the United States and other candidate-centered systems is widely viewed as highly problematic, and much

time and energy are devoted to reporting on it and debating how best to ameliorate its harmful effects.

The demand for and supply of political money are, however, shaped by more than the extent of party or candidate-centered elections. In the United States, the sheer number of contests across the federal system, the separation of executive and legislative elections, plurality rules, constitutional protections of free speech, the high cost of reaching the large American audience, the professionalism and length of campaigns, and the permeability of the policy process all contribute to the large sums raised and spent in election campaigns. The perceived stakes of elections, the incentives and opportunities for raising and spending private resources in campaigns, and the laws and norms governing its role all condition how political money flows in democracies.

Problems Associated with Political Money

Rising campaign costs, scandals, and equity concerns in the early and mid-twentieth century precipitated waves of regulation of political finance and subsidization of party and campaign costs in democracies around the world (Paltiel, 1981). Similar concerns kept issues of the regulation and subsidy of political finance on the public agenda in more recent years. Problems arise as parties and candidates struggle to raise adequate resources to compete effectively in times, when those costs have risen sharply and groups and individuals increasingly seek to influence election outcomes and policy decisions. At one extreme lies bribery and extortion, the illegal linkage of private resources and public authority for personal gain. Short of such explicit *quid-pro-quo* exchanges lies problems, such as the dependence of parties and candidates on large financial contributors, conflicts of interests arising when politicians receive contributions from those who seek favorable action by a legislative or administrative body, and the impact on democratic legitimacy of the actuality and appearance of special access and influence by financial contributors. And then there are the effects of the money chase itself – the unending scramble for political money – on how political parties identify and recruit potential candidates, how party and public officials allocate their time, who they see and listen to, and how both affect the deliberative processes of government.

Another set of problems are associated directly with the electoral process. Rising campaign costs and inadequate political funding depress electoral competition, discourage able people from seeking public office, give a distinct advantage to incumbent officeholders and wealthy self-financed candidates, and weaken democratic accountability by muffling the voices of individuals, groups, candidates, and parties.

A final set of problems arise from the very act of trying to cope with the others. Reforms designed to alter the flow of money in elections often produce problematic unanticipated consequences. Political money is fungible, and legal constraints can divert it to less-accountable passageways. Ambitious politicians and actors naturally exploit the weaknesses and push the boundaries of the law, threatening the effectiveness and credibility, if not, the complete collapse of the regulatory regime.

Political Finance Tools

Policy makers have utilized a conventional toolbox in responding to the problems associated with political money, but the mix of tools and particular applications have varied widely among democracies.

Public Subsidies

In response to concerns about rising campaign costs and excessive dependence on financial contributors, public support of parties and campaigns has become standard among democracies (Katz, 1996). According to the International Institute for Democracy and Electoral Assistance (IDEA), 154 of 214 countries surveyed currently provide some form of public funding to political parties, including 119 countries that provide free or subsidized media. Subsidies take the form of direct cash assistance, the provision of goods and services (e.g., free broadcast time, mailings, voter brochures, and meeting space), and indirect support such as tax credits or deductions for contributions or reduced rates for political advertising. The subsidies are given to parties or candidates, and directed toward party maintenance or campaign expenditures. Direct cash subsidies to parties are typically allocated in proportion to electoral strength or representation in an elected body, while services and indirect subsidies are usually provided on a more equitable basis. In the United States, public matching funds are provided to candidates for their party's presidential nomination, who raise the requisite number of private contributions and agree to limit their spending; full public grants are provided to the major party candidates for the general election as long as they agree to raise and spend no private funds. But unlike most other democracies, the United States provides no free broadcasting time for parties or candidates and no public subsidies for candidates for Congress, although state and local candidates receive such subsidies in some states and localities in the United States.

Public subsidies are not without challenges and risks. In the United States, the voluntary presidential public financing system that began in 1976 in response to the Watergate scandal has been rendered obsolete by the rapid growth in campaign spending. For example, in 2012 the presidential nominee of each major party could have become eligible to receive a public grant of $91 million to fund their general election campaign. By way of comparison, President Barack Obama and Republican nominee Mitt Romney, who chose not to participate in the voluntary public funding system, spent more than $710 million on general election advertisements in battleground states alone. During the 2008 presidential election, Democratic Barack Obama became the first major party candidate to reject public financing for the general election. In 2012, neither Barack Obama nor Mitt Romney accepted public financing for either the primary or general elections. Public financing systems can quickly become outdated if not adjusted to account for changing demands for campaign funds.

Even when adequately funded, public subsidies can reinforce the dominance of established parties, increase the potential for control by the state, and weaken the connection of parties with their grassroots. Public financing, conditioned on very low qualifying thresholds, can also encourage fringe and

nonserious candidates and parties. To the extent that public money is used to subsidize speech or candidates that citizens find disagreeable or offensive, the subsidized speech can itself erode public support for the public financing system. Full public financing systems also generate intense pressure for private resources to find alternate routes to influence elections and policy. To the extent such avenues are available, the ability of the public financing system to alleviate the problems associated with political money is undermined.

Contribution Limits

While public subsidies are the norm in political financing, limits on contributions are less common. Many democracies place no restrictions on the source or amount of contributions to parties or candidates. Among those that do, prohibitions on particular sources (e.g., civil servants, foreign donors, corporations, and unions) are most common. According to IDEA, 38 countries currently prohibit corporate donations to candidates or political parties, 41 countries prohibit union donations to political parties, 40 countries prohibit union donations to candidates, 113 countries prohibit foreign interests from donating to political parties, and 85 countries prohibit foreign interests from donating to candidates.

In the United States, corporations and unions have been precluded for many decades from making political contributions to federal candidates or political parties from their treasuries (with a variety of regimes at the state level), but they may spend their funds to form and administer voluntary political action committees that may raise funds from certain corporate or union personnel and use those funds to make contributions to parties and candidates. But, in recent years, even the long-standing prohibitions on contributions from corporate and union treasuries have been rendered largely ineffectual due to deregulatory decisions of the Supreme Court of the United States allowing unlimited corporate direct spending on election messages, which has led to the emergence of the so-called 'outside groups' that can receive unlimited, and in many cases undisclosed, corporate and union contributions and spend those funds on election advertising so long as they do not directly coordinate their efforts with political parties or candidates.

Some countries have placed statutory limits on the size of contributions from permissible sources, including Brazil, France, Israel, Japan, the Russia Federation, and the United States. According to IDEA, 68 countries currently limit the amount that a donor can contribute to a political party, and 54 countries currently limit the amount that a donor can contribute to a candidate. The contribution limits in the United States are notably low, and even though many of the limits are indexed for inflation, the rapid rise in campaign costs has far outpaced these inflation-related adjustments. This contributes to the extensive fund-raising demands on politicians and creates increased pressure for private funding to flow through other channels, such as 'outside groups,' which are characteristic of problems associated more generally with contribution limits.

Expenditure Limits

A number of democracies place limits on spending by parties and candidates. According to IDEA, 75 of 172 countries surveyed limit the amount candidates can spend, and 51 countries limit the amount that political parties can spend. However, these limits often apply only to a brief period of time (e.g., the formal campaign in parliamentary systems), to candidates but not parties (or vice-versa), or they exempt entire categories of political activity that influence election outcomes. For example, in Japan, candidates for the Diet face limits on campaign expenditures but these are largely irrelevant because they apply only to the 12-day official campaign period. For well over a century, Britain limited the expenses individual candidates for Parliament can incur in their constituencies (and prohibited outside groups from spending on their behalf), but did not regulate political party expenditures at the national level, where most of the action is. However, a law adopted in 2000 limits national campaign expenditures by political parties; it also limits the amount of spending by outside organizations and individuals for political activity during a general election.

Mandatory spending limits adopted in the United States in 1974 were declared unconstitutional by the Supreme Court of the United States in 1976, while voluntary caps tied to the receipt of public funds in presidential elections remain permissible. But, even if presidential candidates were to opt in to the voluntary public financing system and thereby become subject to the spending caps, presidential candidates, political parties, and interest groups would likely work around these limits by conducting political advertisements through outside groups that the courts have ruled may spend unlimited amounts on election advertisements so long as they do not directly coordinate their advertisements with candidates or political parties.

Public Disclosure

Transparency in the flow of political money is embraced by many democracies as an efficient and effective deterrent to corruption or influence peddling, and as a means of providing citizens information they can use to evaluate candidates and to hold elected officials accountable. In 2004, the United Nations Convention against Corruption urged nations to take steps to "enhance transparency in the funding of candidates for elected public office and, where applicable, the funding of political parties." At its core, an effective public disclosure system requires political parties and candidates to disclose assets, income (including contributions), and expenditures in a timely fashion to an independent agency.

According to the IDEA, 125 of 172 surveyed countries currently require political parties to regularly report on their finances, and 103 of 171 surveyed countries currently require candidates to report on their campaign finances. While disclosure of political money is gaining in acceptance in the democratic world – Britain, for example, broke with its long-standing practice in 2000 by requiring that large donations to and expenditures by political parties be publicly disclosed – some Scandinavian countries such as Sweden and Norway continue to consider disclosure requirements applied to election campaigns as an unacceptable violation of privacy.

Even among the countries that have adopted disclosure requirements, however, the comprehensiveness and effectiveness of disclosure regimes vary widely. At one extreme are

systems requiring only the filing of a single report on party expenditures well after the election. At the other are systems, like the United States, with requirements for frequent reporting of political contributions and expenditures (as small as those totaling $200) by candidates, political parties, and politically active groups, and making this information publicly available on a timely basis. But, even in the United States, where there has existed an historic political consensus in favor of disclosure requirements as the cornerstone of campaign finance regulation, a significant amount of electioneering occurs outside the boundaries of the disclosure requirements. For example, during the 2012 elections it is estimated that almost $600 million spent to influence federal elections in the United States was not fully disclosed. Achieving transparency can be complicated by a lack of transparency in a country's broader economy. For example, despite India's relatively comprehensive disclosure requirements applicable to candidates and political parties, a significant amount of election-related spending occurs in India's so-called 'shadow economy' through off-the-books cash transactions. Election authorities have attempted to cut off this 'black money' market by enacting expenditure monitoring measures and even seizing stores of rupees from political parties and candidates, but significant challenges remain. This demonstrates one of the key challenges of public disclosure requirements as regulatory tool: transparency is only as valuable as it is comprehensive. As long as those that desire to have their contributions or expenditures go undisclosed are permitted to achieve that goal – be it due to insufficiently comprehensive disclosure requirements or inadequate enforcement mechanisms – the value of the disclosure system as a whole is compromised.

Regulation of Campaign Activity

One way of reducing the demand for political money is to prohibit or limit certain costly campaign activities. A surprisingly large number of countries ban paid political advertising on television, although, most couple the ban with the provision of blocks of free TV time to the parties. Such prohibitions are unthinkable in the United States, where the free speech guarantees of the First Amendment to the United States Constitution, as historically interpreted by the United States Supreme Court, preclude any significant restraint on political communication. Although the European Court of Human Rights recently upheld the United Kingdom's far-reaching ban on political advertising against challenge brought by an animal welfare group, many other countries have moved to assert that a legal protection of freedom of expression limits the extent to which campaign activity can be subjected to regulation. For example, the Australian High Court declared a 1991 law that prohibited the broadcasting of political advertising during election periods unconstitutional, on grounds that it infringed the implied right to freedom of political communication.

Enforcement and Effectiveness

The success of any measures designed to redirect the flow of or shine light on political money depends upon the ingenuity, comprehensiveness, and timeliness of the particular mix of regulatory and subsidy measures and on the mechanisms for enforcement. Short of blatant violations of criminal statutes (e.g., bribery or extortion), departures by parties and candidates from the letter and spirit of campaign finance laws often go unpunished. Even when violations are pursued, the punishment is often not levied until long after the election during which the violation occurred takes place. Politicians are reluctant to invest the requisite authority in public agencies to enforce political finance laws, a phenomenon tellingly illustrated by the structure and operation of the U.S. Federal Election Commission (FEC). The FEC, whose six members effectively include three from each of the two major political parties, operates under very tight statutory and budgetary reins from Congress and often deadlocks on regulatory and enforcement decisions, as a majority vote of the members is required for the Commission to take action, leading to split party-line votes. Putting in place a reasonable and workable set of regulations, appropriate criminal and civil sanctions, and administrative and judicial mechanisms has proven a daunting task in many democracies.

For all of these reasons, it is not surprising that political finance reforms often fall short of reducing corruption, limiting the influence of monied interests, slowing the increase in campaign expenditures, and increasing electoral competition. Other institutions and policies are, perhaps, more effective levers for combating corruption and enhancing democratic accountability. These include broad economic policies that limit the discretionary authority of public officials; institutions and practices nurturing the rule of law; an independent judiciary; adequate pay and strong ethical requirements and accompanying enforcement for politicians and civil servants; transparent budget and financial control systems; and party systems supporting stable patterns of competition, accountability, and alternation of power (Kaufmann, 1997; Pope, 1996).

Not all political finance measures are doomed to fail, nor are they miracle cures for the ills arising from money in politics. But, since neither the abolition of all private funds from politics nor the complete deregulation of political finance are feasible or sustainable, democracies will continue to struggle not to solve these problems once and for all, but to contain and manage them as best as they can.

Abstract

Political parties are considered as formal civil organizations that are active in public life, in which they represent specific class, professional, or ideological interests, within the framework of the modern constitutional State, and whose goal is to run for election and, upon winning, to take power as the government. There are three nuances of the term 'party' from the historical point of view: rival groups, orders, states, or dynasties; theological or ideological critics; and modern formal social organization. Political parties – in the contemporary sense of the term – became common in the nineteenth century, alongside the development of representative institutions and the suffrage, becoming gradually universal. Parties began to elicit attention from philosophers and the interest of modern historians from the time of the English revolutions of the seventeenth century. A party emerges when a political current within society finds expression through a specific (national or regional) organization. The typical action of parties in modern societies emerged out of the political consciousness that defined and established the notion of a universal citizenship.

The definition of a political party requires a historical perspective. The idea of a party is multifaceted and developed over time, in the prevailing political, social, economic, and (especially) legal realities in which it is formed. In current language – and in the specialized terminology of the social sciences – the term 'party' has been in use for longer than the term 'social class.' Etymologically, the term derives from the verb *party*, which, in archaic French, meant 'partake,' or 'share.' The present article regards political parties as formal civil organizations that are active in public life, in which they represent specific class, professional, or ideological interests, within the framework of the modern constitutional State, and whose goal is to run for election and, upon winning, to take power as the government.

Approaches and Definitions

In the past, the expression 'political party' was also used to describe other political phenomena. Throughout the history of societies and of their political bodies, since antiquity, the expression 'be party to' affairs of public life has been considered a common mode of human behavior. The translators of Aristotle use the term 'party' to designate opposing social groups in Athens. Specialists on ancient Rome have used the concepts of 'Plebeian Party' and 'Patrician Party,' and the famous *De viris illustribus Romae* relates to the party disputes that dilacerated the Roman Republic. The supporters of the Crown and the defenders of the rights of the nobility were also parties. Critics of the theological hegemony of the church and of the clergy were parties within the context of the political order of Christian Europe. Noble families in opposition to the Crown were parties in the marking; religious and political reformers were parties. These are broad meanings of the term that are frequently to be found in the literature. Also under the broad heading of 'parties' can be categorized all manner of social organizations that seek political ends, even if they never stand for (or win) elections, as is the case for the miniparties or revolutionary organizations that have no constituency among the electorate and that do not accept the validity of the electoral system, or even the dominant groups in totalitarian states. Thus, the expression 'political parties' is also often applied to interest groups; propagators of ideologies, doctrines, and political positions; political model makers; and mediators between citizens and government, including a vast multiplicity of bodies that participate in public life.

There are three nuances of the term 'party' from the historical point of view: rival groups, orders, states, or dynasties; theological or ideological critics; and modern formal social organization. The third interpretation has, in part, inherited the historical characteristics of earlier forms, making it possible to make such distinctions as conservative and liberal parties; religious and lay groups; corporative interest and those of the masses; revolutionaries and reformers; left and right; center and radical; and progressive and reactionary. Such distinctions are not exclusive, are directly proportional to the degree of institutional solidity and of integration that the parties enjoy in political society, and always relate to the ideas that separate – or unite – individuals or groups. Such multiplicity is evident in the classification of parties, according to the ideological density of their manifestos, the form of internal structure, competitive or noncompetitive organization, and of party systems (single-party, two-party, or multiparty; unipolar, bipolar, or multipolar) concerning the political and legal frame they are put in. Unlike political science, historical research does not treat these issues in isolation, but rather, seeks to reconstruct how all such aspects relate to each other.

Political parties – in the contemporary sense of the term – became common in the nineteenth century, alongside the development of representative institutions and the suffrage, becoming gradually universal, especially in Western Europe and the United States. In the aftermath of the Congress of Vienna (1814–15), political parties had not yet been formally recognized as civil associations. Any association, assembly, or grouping united by specific goal or political interest was regarded as a party. Conversely, the pursuit of private interests and the application of abusive pressures were regarded as a constraint upon political life, as the goal of winning elections

and of influencing government and public policy became the established criteria for identifying a group of citizens as a political party. In the United States, by the 1830s, parties as such were fully active. In the Western European states, it was in the final decades of the nineteenth century and the first decade of the twentieth century that this development took place. Modern political parties are full players in the public life of democratic societies. In effect, only constitutional states that formed and consolidated over the past 200 years have the institutional framework necessary to ensure regular political participation on the part of their citizens. Such a framework determines the legal principles for party actions, articulates position of the parties in relation to the system of government and the electoral system, and places them within the framework of civil law. Their social origin and ideological orientation notwithstanding, it was the placing of parties within a legal framework that created the party system – understood both as a juridical and political frame of the participation of citizens in political life.

Parties began to elicit attention from philosophers and the interest of modern historians from the time of the English revolutions of the seventeenth century, on through the revolutionary turmoil of 1848, and up until the death of Marx in 1883. They were observed by Bolingbroke and Madison, Hume, Burke, Benjamin Constant and Blüntschli, and the German social democratic thinkers. At the turn of twentieth century, party political phenomena began to be the object of serious scientific methodological analysis. The earliest works in this field were published after the consolidation of parliamentary forms of democratic government, which had been in place since the mid-nineteenth century. The pioneering works of Ostrogorski (1903) and Michels (1911) examined the functioning of parties in the late nineteenth and early twentieth centuries in the United Kingdom, France, and the United States. These authors sought to put forward a general theory, beginning with highly particular experiences and specific historical developments, such as the establishment of federative republicanism of the United States or the burgeoning power of Parliament in the Government of the United Kingdom. There are many descriptive and historical studies on political parties in specific countries and also comparative studies that seek to define possible models. Research trends generally give greater emphasis to the western model of representative democracy, in which formalized parliamentary, electoral, and political party systems play an essential role in public life and the practices of government (Epstein, 1993; Budge and Keman, 1990; Fenske, 1994).

With Max Weber, who couches his remarks on parties from a sociological standpoint, modern political parties came to be understood as a product of democracy and of universal suffrage. Jean Charlot (1971), according to LaPalombara and Weiner (1966), provides a systematically historical view of parties. In order for a group to be regarded as a political party, it should fulfill four requisites. It must (1) possess a visible and stable organization, for the articulation of its local, regional, and national components; (2) ensure continuity of organization, independently of its current managers; (3) have the explicit goal of achieving and holding decision-making power, either alone or as part of a coalition with others, at all levels; and (4) have organizational efficiency, with a view to capturing the vote and harnessing popular support. It is, however, a work by Duverger (1951) that systematizes and compiles knowledge on political parties. Two of his research elements remain valid: one puts forward a theory of the origin and of the proliferation of political parties, from an institutional perspective, relating to the party phenomenon and the dynamics of institutions, whereas the other resides in a typology of parties based on the nature of their organization. After World War II, the discredit and mistrust with which people regarded the traditional political parties of Europe – owing to their failure to avoid the emergence of fascism and totalitarian dictatorships in Italy, Germany, Spain, and Russia – hampered the reintroduction of democracy, and parties were left fragmented and disunited. The understanding came up that healthy democratic life requires political parties within a system of government that establishes clear rule for the formation of governments to exercise the will of the majority, solely on the basis of the judgment expressed through the popular vote. The political instability of the Fourth Republic in France, and of the government of Italy, for example, provided Duverger with a rich material on which to base the most ambitious article written on the theme of political parties in the mid-twentieth century. Duverger regards the parties of the masses as the inevitable product of universal suffrage and regards many of the residual parties as being archaic, especially in postwar France. His view is supported by the movements for ideological concentration in European public life at the Cold War and has as its inspiration the two-party systems – which he regarded as being successful – in the United States, United Kingdom, and West Germany.

Although there is still a lack of broad-based comparative studies, the contributions of Robert Dahl (1966), Lipset and Rokkan (1967), and Epstein (1993) take steps in this direction. The ideological nature of parties is given an innovative treatment by Stein Rokkan, comparable with the contribution of Duverger on party organization. The analysis of party systems was advanced by Sartori (1976) and Blondel (1978), whereas electoral sociology – beginning with the pioneering work of André Siegfried on electoral statistics and geography (1913, 1927), by Richard Rose (1984), David Butler (1981), and Alain Lancelot (1988). More recently, Daalder and Mair (1983), Pierre Avril (1990), Klaus von Beyme (1985), Daniel-Louis Seiler (1986), Mair (1990), Mehra et al. (2003), and Tremblay (2008) have sought to formulate studies from an institutional and systemic viewpoint.

Stages of Development (Phases) Change Over Time

The first expressions of party life began with the defense of specific interests, although in different contexts and times, such as those of the aristocracy against the power of kings and governments, or of the working class against the political, economic, and social dominance of ruling groups or elites. Such defense was not passive. It was carried out by means of consistent and prolonged actions within the representative institutions, such as the estates, consultative assemblies, and parliaments. It also comprised the revolutionary movements in which the respect for rights – both effectively held and merely claimed – was demanded of the political authorities, the governing establishment or the despot.

A party emerges when a political current within society finds expression through a specific (national or regional) organization. The first steps toward the organization of a political group can be observed through the 'parties' into which England polarized in the mid-seventeenth century. Although these parties were still characterized by the discipline and discourse of religion, the political effect of the change from one system of government to another imposed by those in opposition to the power of the throne ushered in a new form of the exercise of power within society. It goes without saying that the great revolutions of the seventeenth and eighteenth centuries – in England, France, and the United States – also gave rise to factions that the majority of historians would call 'parties.'

The typical action of parties in modern societies emerged out of the political consciousness that defined and established the notion of a universal citizenship, evolves in the new space for political protagonists (both for and against the State), the emergence of organized political parties during the nineteenth century and investiture of political parties as being the only protagonists capable of adopting practices, expressing ideas, and taking power and exercising public office within the State. The parties of the bourgeois in the early nineteenth century protagonized opposition between the aristocracy and the monarchy; a similar process can be observed among the emergent revolutionary or proletarian parties of the end of the same century. In revolutionary France, there were embryonic experiences of political party organization: the Girondins, Montagnards, and the Jacobins. The greater part of these 'parties' consisted of small groups, without formal organizational structures. It can thus be stated that no formal parties existed prior to 1820. Three phases in the development of party systems can be identified in the nineteenth century: the earliest phase between 1820 and 1830, an intermediate phase in the 1860s, and a final phase around 1880.

In the 1820s and the 1830s, the British Tories and Whigs emerged and consolidated long-held positions. At the same time, in many countries of Western Europe, and notably in France, there was a movement toward a more constitutional state, expanding suffrage and consolidating the system through application of the principle of majority rule in the formation of governments. It was in this phase that the earliest political parties emerged in Latin America, as in the case of the *Partido Liberal* in Colombia (1815) and the *Colorado* and *Nacional* parties in Uruguay (1836), which arose as an immediate consequence of the wars of independence against Spain and of the ideological influence of the United States. In the intermediate phase, there was a clear expansion of political parties: the Conservative (1840) and the Liberal (1860) parties in Brazil; the Liberal Party in Belgium (1846), the Christian – Democrat and Radical – Democrat parties in Switzerland (1848), the Democratic (1848) and Republican (1856) parties in the United States, the Liberal Party in Italy (1848), the *Partido Radical* in Chile (1863), and the Conservative (1854) and Liberal (1867) parties in Canada.

In Latin America, where most countries had thrown off colonial rule in the first decades of the nineteenth century, only gradually did political parties begin to gain importance. As of 1850, the national aspirations of countries of South America came under the spreading influence of North American two-party system. The first expression of political life was the affirmation of a national identity. The main banner of the 'political parties' up until the mid-1800s was nationalism, defended as the means whereby these new states could affirm their independence in face of their former colonial masters. The 1880s witnessed the emergence of 'classical' political parties, generally in twos, and of either conservative or liberal persuasion – but always nationalist – in the former Spanish colonies. It should be noted that the emergence of political parties did not necessarily mean that they assumed a decisive role in political life. Under the Brazilian Empire (1822–89), a two-party system existed as a means for the rural aristocracy to maintain its hold on power and, under the Republic proclaimed in 1889, this oligarchic system remained essentially unchanged at least until 2003 as the first worker became an elected president.

In the mid-nineteenth century, growing social tensions and bitter social criticism led people with a political outlook to express their social and economic (and occasionally revolutionary) demands through formal political action, by means of the creation of political parties. Thus began the 'socialist' or 'social democrat' phase, typified by formation of the Danish Social Democratic Party (1871), the Spanish Socialist Party (1879), the German Social Democratic Party (1863, 1869, 1875), the Swiss Socialist Party (1880), the Belgian Workers Party (1885), the Indian National Congress (1885), the Austrian Social Democratic Party (1889), the Swedish Social Democratic Party (1889), the Italian Socialist Party (1892), and many others.

World War I forced a pause for reflection and redefinition of the party systems in Europe. The victory (1917) of the Bolshevik Party (1903), which upon seizing power set up a revolutionary and internationalist government in Russia, and, simultaneously, the conservative bias of the Treaty of Versailles (1919) mark the polarization of two separate and irreconcilable ideological currents. On one side, moderate, conservative democratic, and liberal parties found themselves up against hard-line right- or left-wing revolutionary opponents of a nationalist or internationalist persuasion, with scant respect for suffrage, democracy, or tolerance. The twentieth century opened with the founding of a series of communist parties (Russia, 1903; Austria, 1918; Greece, 1918; United States, 1919; United Kingdom, 1920; Spain, 1920; Italy, 1921). These new protagonists on the political scene achieved varying degrees of importance in different places and their role was to become more prominent during the cold War. Communist ideology and the proposals of revolutionary Marxist analyses were to assume the weight of a political mortgage at two moments: in Europe in the 1920s and the 1930s, and throughout the world from 1945 to 1990. Social demands and economic crises deeply disturbed the political environment. The emergence of totalitarian and fascist dictatorships was to undermine political party structures throughout Europe until 1945. Nevertheless, these dictatorships organized political life by means of an imposed adherence to a single party. Only formally such a party was maintained as an element of legitimacy in the exercise of state power, despite the fact that authoritarian regimes could dispense this.

The success of the Western model of parliamentary democracy based upon a three-legged political system (representative and participative democracy, the electoral system, and

the political party system) is thus a recent phenomenon. During the Cold War, the ideals of representative democracy as being the end product of the modern liberal constitutionalism, with roots in the 1790s, appeared to be heritage limited principally to Western Europe and the United States. A few other countries, notably former members of the British Empire – such as Canada, Australia, New Zealand, and India – have practiced representative democracy since achieving their independence. In countries such as Brazil and India, where democratic pluralism exists under specific historical and cultural conditions, many political activities take place outside the formal political party structure.

Between the world wars, growing social awareness of rights and of the need to manage an increasingly literate populace led to structural modifications among the political parties. Economic crises in Central Europe were accompanied by increasing mistrust of parliamentary institutions and the emergence of manipulative right-wing political parties. Fascism and communism radically changed the way in which political parties were regarded. Into the parties of the masses flowed all the social dissatisfaction and frustration, making them easy prey for manipulation by dictators of every stripe. In Europe, as also in other regions, the trend toward mass parties, which in principal appeared to be a sing of the triumph of democracy, in the end generally resulted in quite the opposite effect as authoritarian rulers assumed power. In many regions, however, expectations with respect to the freedom to participate in party activities were enhanced, especially after the experience of World War II.

The triumph of the Western model of liberal democracy with parliamentary representation was one of the consequences of the new international order that emerged after 1945, except in regions under the yoke of communism (Eastern Europe, China, and Cuba). Communist regimes, however, do not dispense with mass parties or even with formal parliaments, although the role of these institutions is merely figurative. After World War II, a new phase of political life began, with the restoration of the values of liberal democracy, universal suffrage, civil liberties, and parliamentary representation. The Western tradition of recording political events – at least since the Code Napoleon (1804) and the British Reform Act (1832) – has provided a framework for the organization of political life in such a manner that the formal and legal structuring of parties has advanced in parallel to the campaign for constitutional government. This has caused parties to organize and represent themselves as both defenders of an overall social vision and as pursuers of political goals. Thus, parties assume the posture of political businesses whereby they compete within a legal framework to advance the political convictions, opinions, and beliefs – and to defend the preferences and class interests – of their constituents. Diverse and intersecting interests find expression among groups, clubs, associations, and, above all, political parties. The social economic and ideological cutlines present in the social structures were key factors throughout the nineteenth century. Conservatives and Liberals, labor parties and revolutionaries, opposed each other in Europe and also in Latin America. In the United Kingdom, the Conservatives and the Liberals succeeded the Tories and the Whigs and were in turn superseded by the Conservative and Labour parties of the twentieth century. In the United States, in the period following the Civil War, the Democrats and the Republicans definitively consolidated their hegemony over the political scene (Katz and Mair, 1992).

The history of political parties clearly demonstrates that the political opportunities in the social competition for power in the State have an effect upon the parties that, for their part, have an effect upon the structure of political opportunity, i.e., parties and institutions mutually affect each other. In democracies that work regularly, disciplined voters arise, as in the European Union, for example. These voters do respond to party activities, although they are increasingly critical of the means whereby parties pursue their ends. 'Belonging' to a party tends to be more a sociological identification with a political tendency, rather than involving formal party affiliation. This suggests a salutary clarification of the boundaries between parties and their environment. The process whereby a party is identified with its leader is an interesting historical phenomenon in the political organization of societies. For example, the Braybrooke Manuscript (1788) refers to the parties 'of the Crown,' 'faithful to Mr. Pitt,' and 'of Mr. Fox.' Another interesting and more contemporary example is of the emergence of a 'Gaullist' party in France, after 1946. The tradition of having a strong personal leader continues very much alive in Latin America, even in the late twentieth century. This tradition has influenced the social practices of parties in various ways. In Mexico, the Institutional Revolutionary Party – PRI (1911) – dominated the Mexican political scene single-handedly until 2000.

With the advance of democracy and of democratic negotiating practices, conducted with a view to making government of contemporary states feasible, all parties (including the new parties that emerged out of the former communist parties of Eastern Europe, and also certain parties in Western Europe) have had to become connected. The difficulty of winning elections based solely upon their different platforms and making their will prevail has, since the 1970s, obliged parties to emphasize their capacity to draw together to form and support coalitions. Finally, all modern parties are obliged to adopt businesslike organizational structures or run the risk of failing to fulfill the demands of modern life, in terms of communication, social penetration, and funding.

Evidently, the aim of assuming the mantle of government remains the principal motivation of political parties. The historical trajectory of activities undertaken by political parties is closely associated with an awareness of the structure of political opportunities within a given political system. Revolutionary organizations that reject existing institutions, social clubs, debating societies, pressure, or advocacy groups with independent objectives can be regarded as entities that discreetly play significant political roles without being formally political parties. Formal political parties must, as such, compete to control a political process whose agenda they do not establish by themselves, but which cannot function without their participation. This experience is deeply ingrained in the political parties of the late twentieth century.

Unanswered Questions and Issues for Debate

Some important questions remain unanswered. For example, the emergence of political participation – as an alternative to

traditional in liberal democracies – is often treated both as an essential element for modernization and as its critical consequence. To assume the mantle of government and to perpetuate the values of parliamentary democracy, strong parliamentary institutions are necessary if modern political parties are to perform their roles. This is true even in countries such as the United States – and many others in Africa and Latin America – in which the presidency is a strong and 'personalized' institution. This applies even in cases where presidents are elected by direct vote and are endowed with special powers, as occurs in France and Portugal.

Although much is known with respect to the details of the emergence of specific party systems, the capacity to generalize as to the reasons why different types of parties emerge in the ways and forms in which they have done so remains incipient. There are few works that examine or seek to explain the vast variety of different contexts, and comparative studies among regions with different levels of development are rare. In the 1980s, the political development of multinational regional institutions – which initially had a solely economic focus – such as the European Economic Community, Association of Southeast Asian Nations (ASEAN), and (in the 1990s) MercadoComum do Sul (MERCOSUL), has unveiled a whole new field for research into the political life of such institutions, their relations with member states, and the entire theme of supranational integration. From a historical research perspective, only now are the first comparative studies of the political parties being carried out. This applies not only to research on existing parties in specific countries or groups of countries (as is the case in the European Union) but also with respect to an examination of the historical roots of contemporary political parties.

Not only parties but also party systems can be analyzed from the institutional standpoint. Both the parties and the party systems of the 1970s were little different from those of the 1920s. With the exception of the ecological movement, the majority of the party groupings, i.e., similar parties, can be presented according to their similarities. Practically all the present parties – of the left, of the right, and of the center; liberal; and revolutionary parties – consolidated themselves in the 1920s, and some much earlier. Political parties are present at the heart of all activities of the state in liberal democracies. However, even under communist regimes the role of the political party is performed in a well-established manner. In the 1990s, however, it could not safely be predicted that political parties would face a future with development and prestige, similar to that they enjoyed in the recent past. At the present time, a new type of political culture is emerging. Political awareness and politics – as subject for discussion – open up a new avenue of research into general participation in political life on the threshold of the twenty-first century. Culture may help in understanding as to why certain social cleavages are successfully transposed by a stable party system, whereas others are not. Political culture and the manner in which it is created are responsible for some significant differences in the traditional organization of states, or of bodies associated with them. Political culture includes not only ideals, such as values, beliefs, and attitudes, but also political practices and societal behavior.

There are certain themes in the study of political parties that still require further research from a historical point of view. At the present time, issues on gender representation, minorities' rights through political representation, religious militancy in politics, and reevaluation of subnational or national claims within historically centralized states won on importance and political relevance. Therefore, the question of the balance in the use of political power and the politics of containment became recurrent themes in political science and in history as well. One of the most important contentions of political activity is the institutional framework of the state. Contemporary political and historical research has made clear the importance of institutional factors in political life. Aside from this new institutional focus, the study of political parties has demonstrated a renewed appreciation of history, of events, of the rule, and of political regimes as the active forces of political life. It is perhaps commonplace to state that 'history matters.' The 'frozen cleavages' of Lipset and Rokkan, the development models of communism, fascism and the parliamentary democracy of Moore (1968a), and the theories of 'critical realignment' of Burnham (1970) are good examples of historical reviews and models. The legacy of history is thus one of the limitations to which institutionalism is subject.

Socioeconomic constraints are generally accepted without going into the mythical and overworked concepts that have been served up since the time of Marx. Rapid changes in international finances and economic scenarios have produced intriguing works. The exercise of social power is also constrained by cognitive means, in the use of pure reason (and more specifically, of the practical one). The knowledge society and information society will have to take into consideration nonrational features of political life, and the social and ideological factors that influence the belief systems of the masses (Meny, 1989). The final two decades of the twentieth century witnessed a swift retreat in the positivist distinction between fact and value. Specialists recognized that political agents were also ethical players (Rawls, 1993), who have their own values and act in accordance with them, and that occasionally they may be persuaded (by political philosophers, perhaps) to adopt other, better values. Any attempt to divorce facts and values from the mental processes and from the underlying political dynamics would be doomed to failure. Similarly, political science increasingly seeks to develop studies that take into account the complexity of the structures, processes, and results that it investigates. In order to do this, one must have a theoretical framework within which the history of the processes and the prevailing political philosophy must occupy a space that formally would have drawn opposition from previous generations.

Abstract

Communism is a loosely used term applied to a variety of political parties, but in this article the focus is the Communist Party as established and run by Lenin and its organizing principle of democratic centralism and relation to the Soviet Union. These parties were parts of the world Communist system and had the vocation to run the societies that they took over, whether by revolution as in Russia itself or put in power by the Soviet Army as in the Eastern European regimes.

In the discussion of the Communist Parties, several issues need to be disentangled. In the first place the Communist Parties are Marxist Parties, but the Marxist vision of industrial society was appropriated by most of the left-wing Socialist movements in the late nineteenth century and Marxism (with a few exceptions) became the common property of the left in different versions. Thus, at that time, many parties of the left would have claimed to be 'Communist Parties' and 'revolutionary' without having links to the Russian Party or Moscow's institutions. Secondly, Communist Parties were organized on the basis of 'democratic centralism' and that distinguishes them from other Socialist parties of the left and from their rivals. Thirdly, Communist Parties were established to support the Russian Bolsheviks after Lenin's 1971 coup d'état (in orthodox Communist parlance the 'October Revolution'), and subordinate Communist Parties formed parts of a worldwide system until the collapse of the Soviet Union itself. Their *raison d'être* was the defense of the USSR, the land of 'really existing Socialism,' the workers' fatherland where the Socialist society was being built. Thus their lodestar and guiding principle was the defense of the Soviet Union as defined by the Russian Communist Party's institutions in Moscow.

Communist Parties claim to be the authentic interpreters of Marxism but, of course, their views should not be confused with Marx's philosophy, which is a social theory about the coming revolution in industrial societies. In it Marx argued that the working class would be subject to such oppression that they would ultimately be forced down below the threshold of poverty and then would rise up and overthrow capitalism. Thus freed from capitalism, the workers would install a new (Socialist) society that would in turn lead to Communism. Socialist society, in a phrase used by Communist Parties but (having poisonous connotations) dropped latterly, was the 'dictatorship of the proletariat.' But the proletariat, or industrial workers, having no ulterior or selfish interest, would free humanity from oppression. Marxism is thus a theory of revolution that predicts how the revolution will happen and which class in society will carry it out. It does not say anything about how to organize revolution, the future society, or how Socialism is to be run. In fact, as Popper pointed out, the very flimsy depiction provided by Marx of the Socialist society is one that looked somewhat like mid-twentieth century Europe and not a Communist utopia. However, crucially, Marx does not say how the revolution is to be accomplished and Marx does not provide a handbook for government. Marx ignored the crucial political problems of how to take power and how government should be organized. These, Marx assumed, would be spontaneously solved or painlessly resolved when the class of the future, the proletariat, took power. Initially Communist Parties had a naive view of the state and organization, but Lenin developed the theory and practice of the Revolutionary Party: the guide and tutor of the working class leading it to its vocation to liberate humanity, and the ruler of the Socialist state. Alone, without the Communist Party as its vanguard, the working class would not rise to its mission and would content itself with minor reforms (Lenin *What is to be done?*).

However, by the turn of the nineteenth century the big European Socialist parties had realized that the prediction made by Marx was wide of the mark by a substantial margin; European society was not getting poorer and the propensity to revolution was absent from industrial settings (there were dramatic demands about wages and conditions). During the first decades of the twentieth century, for many on the left, the theory of 'revolution' as set down by Marx was abandoned or watered down by many mainstream left wing parties.

The Leninist Party

Lenin, an isolated figure before the First World War but the sovereign theorist of Communist Parties, maintained the 'revolutionary faith' and the Party was fashioned to implement that vision. Lenin's Bolsheviks, a faction inside the Russian Social Democrats, were organized around obedience and discipline. This organizing principle is 'democratic centralism' and changes in doctrine and alliance are secondary to this practice. Adoption of this 'democratic centralism' was the seventh of Lenin's 'Twenty-One Conditions' that local Communist Parties had to accept to be admitted to the Third International. In June 1921 the Komintern declared that the Communist Parties were the directing army of the proletariat through capitalism and socialism into Communist society. As it is usually formulated (and it is not the subject of extended exegesis like other Communist precepts) democratic centralism may appear to be straight forward: it is described as something like open discussion and then unity around the policy, once it is decided. In practice it is highly centralized and dictatorial, providing leaders with a paramilitary structure. Any criticism of the leadership and its prevailing policy

can be denounced as 'factionalism' and as aid to the class enemy (Carew-Hunt, 1950; Kolakowski, 1978).

In addition, at the Communist Party's core were professional bureaucracies staffed by a narrow group, in reality appointed by the leadership from the top. Communist Party practice amounts to a militaristic discipline and the execution of orders. In 'democratic centralism' lower bodies are subordinate and submit to the higher organs, and contacts across the base of the party or members grouping together are outlawed as 'factional activity.' Internal criticism is severely constrained and the internal elections amount to nomination by the leadership. Promotion depends on the leadership. It is a hierarchy that mimics 'bourgeois society' but the elected Communist representatives (parliamentarians, for example) will be low in the structure and under the purview of superiors in the Party.

Trotsky, before joining Lenin's Bolsheviks, was one of the first to observe the consequences of 'democratic centralism': "Lenin's methods lead to this – the party organisation at first substitutes itself for the party as a whole. The central committee substitutes itself for the party organisation, and finally a single man substitutes himself for the central committee" (Waller, 1981: p. 117). Lenin, who was surely aware of this dynamic, fashioned the Party for himself although it was taken over by Stalin, Lenin's 'magnificent Georgian.' It was 'democratic centralism' and not revolution that was the main contention on the left after Lenin seized power. Communist Parties, established on Leninist lines, were also the embryo of future society and, in this sense, were 'totalitarian' parties destined (where they came to power) to control all aspects of society. In a way the Communist Parties, without the familiar Browning motion of political parties, are instruments for revolution and control, and have eliminated the politics of negotiation, bargaining, and debate as it is usually conceived in open societies (Polan, 1984). In this way, trade unions, for example, become the instrument of the Communist Party (the 'transmission belt' to the masses); and fronts and pressure groups in the Communist orbit functioned in the same way, promoting Communist Party positions, though tailored to the particular audience (peasants, industrial workers, women, peace movements, and so on).

Communist Parties have, in ideal type and as a general model, a pyramid structure with the apex – leadership – issuing orders. At the base of the Communist Party is the cell (sometimes called the 'primary party organization') formed with three or four Party members. These small groups are for electoral purposes and are usually organized in electoral districts; but this was not the priority (the basic unit being electoral in other parties) and cells were usually set up in factories, farms, recreational organizations, and workplaces. Cells have a Secretary and receive instructions from the hierarchy but cells are isolated from each other and cannot campaign or develop policies contrary to those of the leadership. This is a robust system that enables both control by the leaders and clandestine activity by members who are *in partibus infidelium* – in capitalist society – or who are controlling society in Communist Party states. Further up the pyramid there will be a Federal Committee, but at the top are the Central Committee, a Political Bureau, and above that is a small Secretariat. Central Committees, sometimes misleadingly called the 'parliament of the Communist Party,' are 'elected' by party congresses and in turn designate the small Political Bureau and the smaller Secretariat. These elections are in reality nominations with one candidate provided by the Secretariat and are invariably unanimous.

Party debates are severely circumscribed and opposition, if expressed, is isolated and crushed. Communist Congresses are characterized by unanimous or near-unanimous votes (usually taken in public with a show of hands) and so are the votes of higher bodies. Because the Secretary General has the power of nominations, the central figure in the Communist Party (outside times of 'collective leadership' when no dominant figure has emerged) is the Secretary General. Moreover, the Secretary General emerges from the central core apparatus of the Communist Party bureaucracy. This apparatus regularly produces the 'prodigious mediocrities' that run Communist Parties and Communist states.

This pyramid of power is run by the central apparatus that Lenin established: the professional revolutionary. Communist Parties are essentially the central core around which are wrapped the activists and front or parallel organizations. Importantly, discipline also enabled the orchestrating of campaigns and the simulacrum of grass roots upsurges in opinion. This professional core is the lever with which Lenin intended to move the world. Communist Party functionaries, 'apparatchiks,' are nominated, promoted, and made by the leaders and, like the Duke of Newcastle's Bishops, they worship their maker. Full time organizers and workers on the Communist Party payroll play a very important part in Communist politics and are a powerful resource in an area of social life that is rarely organized and depends on amateur or volunteer support. Thus, in a fully developed Communist Party the main posts will be held by people who have ascended the apparatus and who are capable of taking orders and applying them with vigor and efficiency (however, counter-intuitive they may be). This structure may not be evident to all of those working in the Communist Party and Party employees are described as 'workers' in industry. It is, of course, a larger establishment than other parties and is expensive to run. Subsidies from the Soviet Union and control of trade with Soviet satellites were important in the past but the local Communist Parties developed resources of their own (local government and unions, for example).

Third International Parties

It was the First War that gave the far left its crucial boost and the Bolsheviks, led by Lenin, were able to take advantage of war weariness and increasing privations. But the Russian Revolution also raised a major disagreement that crystallized on the socialist left after 1917. When the Lenin's (Communist) Third International was set up in 1919, Western Socialist Parties determined that the route to future progress would be electoral and endorsed the rights in the constitutions of modern states. By the mid-twentieth century, all but a few of the Socialist parties in Europe had abandoned Marxism even in watered-down versions and it was left to Communist parties, although other minor splinter parties also laid claim to Communism. (McInnes, 1975)

After the Russian Revolution the Western Socialist parties supported the new government. Tsarist Russia, corrupt and

repressive, had few friends on the left wing of politics and the installation of a Socialist government under Prime Minister Kerensky was hailed as great step forward. This support generally remained after Lenin deposed the Social Democrats and installed the Communists (Bolshevik Party) in power. There was a degree of confusion on the left because Lenin appropriated the Revolution and support for the new Russia was widespread. When Communist Parties were founded in the early 1920s, many former pacifists and idealists joined on the assumption that they were joining a new formation dedicated to defending the Revolution, but essentially a more determined variant of the Socialists. There followed a period of 'bolshevization' of the Communist Parties, which saw the eviction of the initial leaderships and the installation of Moscow loyalists.

This is where the distinctive features of the Communist Parties become crucial. Parties were centralized and disciplined where possible (local difficulties, like civil wars, meant different rates of progress). This process of so-called 'bolshevization' took place under the auspices of the Third International executive in Moscow, the Komintern founded in 1919. In this, the local elites who had rallied to the Third International were replaced with Moscow's reliable cadres. Those who joined in the initial wave were often at odds with the Komintern outlook: usually because they were admirers of the Russian Revolution who had joined out of antiwar sentiment, because the Socialist Parties did not – as they saw it – defend workers sufficiently vigorously in the postwar recession, or in the upwelling of idealism that the Communist Parties tapped into. In this phase of development the Communist Parties, where they were free to do so, set up their own unions and competed directly with the 'reformist' Socialist trade unions and Socialist parties. Trade unions were alerted to this threat and in many industrial countries perceived Communist Parties as hostile to unions and to union influence.

Communist Parties had a vocabulary that portrayed them as the artisans of working class unity and as the most advanced part of the proletariat. They would not allow that they were the factor of division of the proletariat but that other malefactors or class enemies were, through 'false consciousness' or 'economism' (devotion to short-term wage increases and the like) disrupting the unity of the class with the revolutionary vocation. But the Communist lexicon enabled a considerable tactical flexibility. Communist Parties could emphasize or downplay parts of the Marxist message according to circumstances. Churchill said that the Communist Parties zig-zagged but you never know whether they were on a zig or a zag.

It was the Soviet leadership that decided the exact tactics that parties would take. Communists differentiated between 'unity from below' and 'unity at the summit.' 'Unity from below' was an attack on 'bourgeois society' and its outriders the Socialist Parties and unions; and 'unity at the summit' involved collaboration between parties and non-Communist institutions (which could be conservative or Christian) in pursuit of some aim. Communist Parties at this time took a revolutionary line in which the Socialist Second International Parties were the principal impediment to the working class realizing its revolutionary potential; and attacks on 'Social Fascists' continued even after Hitler came to power in Germany.

From 1917 and until the late 1920s Communist Parties were set up, usually by enthusiasts for what they saw as the Revolution's ideals. These parties sent delegates to the Third International (Komintern) in Moscow and formed the nucleus of the world Communist movement. Komintern's establishment of its authority in the mid-1920s created the hierarchical and bureaucratic Communist Parties under the Komintern Executive Committee with, usually, local leaders placed in position by Moscow. This 'bolshevization' should not, as is often the case, be confused with stalinization. A power struggle in Moscow after Lenin's death saw the emergence of Stalin as the Soviet Party's leader, and many on the Komintern Executive had been opponents of Stalin's rise or not enthusiastic about him. Stalin's preponderance was signaled by a change of line to 'Socialism in one country' which recognized the failure of revolution in Europe, and the focus on the defense of the building of Socialism in the Soviet Union. Leaders like Zinoviev were replaced and reliable placemen installed. This process of eliminating the unreliable that Lenin urged and which he referred to as 'purges' (sometimes loosely referred to as 'stalinization') took place both in Moscow and at the national level, although many leaders changed horses convincingly enough to be retained. They had usually worked to convince the Moscow leadership of their reliability and willingness to execute orders, however suicidal from a local point of view they might appear to be. Palmiro Togliatti, the Italian official who apparently had Stalin's ear, was superior to other Europeans in the Komintern hierarchy and may have had greater leeway than others. The French Communist Party leader Maurice Thorez, although leading the biggest Communist Party, was subordinate. Georgi Demitrov, the Bulgarian Communist, took over as the head of the Komintern Executive and in the 1930s there were purges of foreign Communists who were, in some cases, handed over to enemies.

In 1928 Stalin's increasing domination was behind a further change in policy to 'class against class' sectarianism: the aggressive attack on 'bourgeois' institutions and the repudiation of the big working class parties ('Social Fascists' in Communist terms) and institutions on the grounds that the capitalist crisis was entering its final phase of convulsion. This policy, disastrous for local parties which lost support, meant vigorous attacks on the Socialist Parties and led to the rise of Nazi Party, which Communists persisted in seeing as an epiphenomenon (Mortimer et al., 1979: Chapter 2). However, the rise of Hitler could not be dismissed in this cavalier fashion and a U-turn in policy to inaugurate cooperation against the Hitler Right was introduced by Moscow in 1934. This was the 'Popular Front' strategy intended to bring together all anti-Nazi forces: these forces were mainly the Socialist Parties but the strategy was a Soviet foreign policy *demarche* and not a domestic, local, one (Joll, 1959: p. 56). Hence the range of the appeal was not limited to the left and the Communists, and in pursuance of this objective, the Popular Front strategy stripped out the radical elements of their appeal and rhetoric and emphasized the patriotic and national elements of politics. Thus the reforms with which the Popular Fronts are sometimes credited, were Socialist and not Communist in origin.

Although Komintern was dissolved during the Second World War in May 1943 in deference to US and UK Allied sensibilities, the change was more apparent than real and the central control of the Communist movement was maintained through the International Department of the Central

Committee of the Soviet Communist Party. However, Stalin's control, although indirect, remained the guiding force for the Communist Parties. After the Liberation, Stalin's immediate priority appears to have been the establishment of Communist Party control in the countries overrun by the Red Army in Eastern Europe, and the Western Parties played a low-key and accommodating role in reconstruction. This changed when the United States returned to the European arena in support of the non-Communist countries and the line again changed to one of aggressive attacks on 'bourgeois' institutions. This was established in September 1947 after the Marshal Aid programme was implemented by the United States, when the Kominform was set up (Marcou, 1987).

Kominform was to inaugurate a new offensive line in Western Europe that saw the Communists orchestrate strikes and riots in many countries in opposition to the Marshal Plan. This new line probably took the Western Communist Parties by surprise and the delegates from France and Italy at Komintern's Szlarska Poręba first conference in Poland found themselves in the dock, subject to volleys of abuse for lack of revolutionary spirit. Despite the creation of this new focus for Communist Parties, the Komintern was less important to parties than direct relations with the CPSU International Department. In 1956 Khrushchev dissolved the Kominform and the CPSU's International Department took over the office of coordination. This process was assisted by the editing committee of the journal *World Marxist Review* published in Prague after 1958. The *World Marxist Review* was a largely Russian enterprise but was destined for Communist Parties across the world, and it set out the Communist position coordinating Parties on issues of the day, until it was wound up in 1990.

Postwar Fortunes

At the Liberation, the second wave of Communist electoral growth began and the emergence of the Communist Parties in France and Italy as major forces was consolidated. In Southern Europe, Portugal, Spain, and Greece, Communism emerged from the dictatorships and became electorally significant. The mechanism here was probably similar to the Second World War Occupation in France and Italy: the Communists, secretive and well-suited to clandestine work, were the principal opposition to the occupations and to dictators and benefited from being the main opposition to the regime in these countries. If people were disposed to struggle against the dictatorships they would very likely find themselves in the Communist ambit – if not the Party itself – and participating in an opposition portrayed as patriotic first and Socialist/Communist second

Khrushchev, however, changed the Communist Parties' line and moved to peaceful coexistence and an understanding based on the nuclear stalemate in Europe that froze the two blocs until the late 1980s. Communist Parties, henceforth, would seek the 'parliamentary road to power.' In the history of Communist Parties and in Western Europe, the key date is 1956 when the Communists changed tactics from revolution in Europe to the 'peaceful road to power' through parliamentary elections. This was Khrushchev's repositioning strategy and reflected a *realpolitik* recognition of the balance of power in Europe, and by contrast, the revolutionary possibilities in the decolonizing European Empires in Africa and Asia. Khrushchev's strategy was, it was stressed, not to be confused with the 'parliamentary cretinism' of the Socialist Parties. Socialists put all the emphasis on reform through 'bourgeois' institutions, in the belief that a more moderate form of capitalism could be developed that provided welfare and security without destroying the market mechanism. Communist Parties did not accept this 'sell-out.' Communist Parties were expected to use the opportunities of 'bourgeois' institutions without abandoning their ultimate revolutionary vocation.

Hence Communist Parties in Western Europe began to seek partners within the party systems of Europe for coalition alliances and this meant – inevitably – targeting the Socialist Parties. However, Socialist Parties had broken links with the Communist Parties in the Cold War and were suspicious of Moscow's intentions. With the memory of the take-over of Eastern Europe and with Communist coups in mind (and those with close union links were aware of the suppression of unions in the Soviet bloc), there was no rush to seal deals with the Communist Parties. Communist Parties seeking alliances were largely unsuccessful and they met notable rebuffs in Italy, Spain, and Portugal; and only in France was there a modicum of success with the formation of the Socialist-Communist Common Program alliance in 1972. In 1981 President Mitterrand offered the Communist Party four minor ministerial portfolios in a Socialist-dominated government (that had no need of Communist support). When they quit 4 years later the experiment was terminated.

If Khrushchev's strategy had meager returns, it did help to loosen the ties of the Communist Parties with Moscow. There was a tension in the Communist strategy of alliances within a parliamentary system: local Communist Parties had to show that they were not controlled by Moscow and this led to the 'Eurocommunist' interlude in the 1970s. Communist Parties in France, Italy, and Spain announced their differences with Moscow (and even picked quarrels) in order to demonstrate their patriotic autonomy. This was, however, more a presentational device than a real independence. However irritating it was to the CPSU and to Moscow loyalists, the divisions were superficial and cosmetic. Thus the Italian slogan 'NATO out of Italy, and Italy out of NATO' may have looked even-handed, but the Warsaw Pact forces which suppressed uprisings against the Communist Parties in East Germany, Hungary, and Czechoslovakia were on the continent and under Soviet control. Likewise the protests against the Cruise and Pershing missile bases set up in the 1980s were in historical fact a response to Soviet missile deployment and not a one-sided NATO initiative. To some extent this tension between the USSR and local Communists subsided in the 1980s, when the French Party supported the Russian invasion of Afghanistan, the Spanish Party imploded, and the Italian Communist Party lost support.

Communist Party Control

In government the Communist Party's top-down command structure and its permeation of society constituted a control mechanism for the whole of society. In a Communist state, the so-called 'People's Democracies,' government departments, and civil society were under the oversight of the Party and

under its control, with the result that a highly centralized and responsive state–society relation was constructed, but one at the command of the leadership. Communist Party control of civil society more or less eliminated intermediate institutions and those that remained were subordinate to the Party state. This was not a once-for-all process and the incorporation of institutions into the Communist system took place with varying degrees of efficiency and some, such as the Polish Church, never fell under Party control. However, the Party supervised and ran the ostensibly independent trade unions, writers' organizations, theater and film makers, and so on. In the production of the economic plan this central control was crucial: the Party took over and ran the factories and workshops and independent businesses with only peasant agriculture (partially in some countries) escaping this extensive control.

In its developed stages in the Soviet Union, this party–state interaction was a coherent and almost monolithic structure with internal dissent subdued and usually eliminated. As the system matured, the establishment of 'baronies' in regions or in some sections of society and industries began to emerge and the control by the center weakened, although the central command structure and the Party organization was still the central feature. Communist Parties found it increasingly difficult to maintain central control and to devolve power to enable innovation and initiative, with the result that the system did not bend under pressure, but broke. Whether the remaining Communist Party systems can introduce the flexibility required by marketisation of the economy and retain an absolute political dominance remains a moot point.

Electoral Support

Though they have not neglected the electoral arena, traditionally, Communist Parties have not regarded the electoral arena or parliaments as the key to political power. In the major societies the Communist Parties have usually been marginal, where there is a system of competitive elections; and before the Second World War they had a party system impact only in France, Germany, and Finland. In the 1930s there was not a great deal of electoral success and in many countries they were outlawed. After the Second World War they had more success, but in open societies few Communist Parties were major components of the left and in only Finland, France, and Italy (and Cyprus later in the 1970s) were they genuine mass parties. In the late 1940s the Communist Parties had some success claiming to be the most advanced part of the Socialist movement and promising peaceful change; moreover they had the prestige of the USSR, a victorious ally, and the Soviet system (about which at that time little was known by most people) behind them. In many countries they made a respectable showing at the polls perhaps winning 5% or more after the Liberation: over 28% in France, 23.5% in Finland, 13% in Belgium, and 12.5% in Denmark. (Setting aside such minuscule oddities as San Marino, where the Communist Party polled 42% in 1949.) Elsewhere they were sect-like but adept at infiltrating unions and organizations or running fronts, if not at winning votes. (McInnes, 1975) In some countries, Germany, the USA, Canada, Australia, New Zealand, and the UK notably, they made no electoral impact whatsoever. This slight ascension of the Communist Party vote was reversed with the onset of the Cold War and in most countries they were, by the 1950s, reduced to groupuscular status. Communist Parties were successful when they were presented as social democratic parties, promoting reform and workers' rights, but when they were hostile to Western institutions and vaunted their attachment to Moscow their vote fell or was reduced to virtually nothing.

Not the least of the paradoxes of the Communist Parties (the parties of the working class) is that the successes, such as they were, came in the 'wrong' places: in the backward and peasant countries of Russia, China, Vietnam, and Cuba. In the mid-twentieth century (during and after decolonization) the Communist Parties made their advances in the backward and peasant societies of the Third World – Africa in particular – but not in the industrial world. Marx's theory was about the development of mature and decaying capitalism and, if the theory had been correct, the site of revolutions would have been the advanced industrial countries, such as Germany, the USA and the UK where, as Marx saw it, the newly emerging proletariat in the factories and workshops would sweep away the old systems. Even in Western Europe the Communists found themselves positions in the mainly poor agricultural areas, in traditional industries of mining, steel, and coal and to some extent in the public sector. Electorally the same paradox appears in that the Communist Parties were strongest in the poor agricultural regions like the borders of the Central Massif in France, North Finland, the Alentejo in Portugal, and the declining heavy 'rust belt' industries of coal, steel, and textiles. Communist Parties, despite the emphasis on science and progress, were part of the nineteenth century sectors and found it impossibly difficult to break into the new science-based and information-based businesses.

Post-Wall Communist Parties

In Europe after 1992, it needs to be said that the collapse of the Soviet Union caused the parties identifying with Moscow to transform themselves into quite different party organizations or to claim to be new in some respect. Hence it is difficult, in the absence of a Communist International, to say precisely which are Communist and which have moved away from the initial model . Very few, even of the post-Communist Parties, retained 'democratic centralism' as an operating system, although there are a number of Trotskyite parties that claim to be the 'real' inheritors of the Communist message and which are Leninist. In the twenty-first century, those proclaiming themselves as Communist parties include the former Soviet loyalists who emphasized the original vocation in Spain, Portugal, Greece, France, and the Third International dissidents – Trotskyites – who have not abandoned their ancient rancors. Other Communist Parties became part of rainbow alliances of ecologists, decentralizers, and new leftists in minor parties. (Courtois, 2011: Part 4, esp. Chapter 23)

Governing Communist Parties, in the Eastern bloc but also in the Soviet Republics and the East, also repudiated the Soviet past and transformed themselves into something else: this was usually as a Socialist Second International Party, and the Communist Parties in their initial incarnation disappeared.

There are exceptions: the best known are North Korea, Cuba, and China where the ruling Communist Parties have not experimented with open elections and where the solidity of the one-party state has remained intact. In North Korea the military state remains intact but under the façade of the Communist Party and its long-running dynasty. Cuba has opened sectors to the outside but remains a one-party state organized around the remaining revolutionary elite (Rigoulot, 2007). But China, the most innovative of the post-Soviet states, has, by unleashing market forces in the economy but remaining in control of the political institutions, found new ways to shore up the totalitarian system. One of the unknowns about the remaining state Communist parties is whether they can manage a transition to a market economy while maintaining the pervasive political domination of the Communist Party (Kissinger, 2012). This proved impossible in the Soviet Union and its satellites but a one-party state running a market economy ('market-Leninism') cannot be excluded.

Political Parties: Extreme Right

Christopher T Husbands, London School of Economics and Political Science, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article describes how 'extreme right' became part of the vocabulary of political science. It discusses the introduction of the cognate term 'radical right.' It offers its own comprehensive definition of extreme-right parties intended to cover a range of examples in different locations since the early nineteenth century. It discusses whether some parties labeled by many authors as 'extreme right' or 'radical right' ought rather or also to have 'populist' as a component of their labeling. It periodizes twentieth and twenty-first century extreme-right parties and discusses theorizing and research on the extreme right. It focuses first on debates about German Nazism, discussing contemporary and more recent theories about it. Various theories about postwar extreme-right parties are then described. Findings about the social base of extreme-right parties are summarized. Alternative forms of extreme-right movement are described. The tendency of extreme-right parties to splinter is discussed. Finally, some possible trajectories about the future of extreme-right parties are introduced.

Political parties that current conventional labeling by many political scientists and other informed analysts describes as 'extreme right' have emerged in many countries and on many occasions since at least the early nineteenth century, notwithstanding a debate about appropriate descriptors. The label, as employed in this article, is necessarily an encompassing one because it is applied generically to numerous parties that nonetheless differ from each other in various ways and on to which, in some cases, not every recognized specialist is willing to confer such a label.

The Term 'Extreme Right'

The word 'extreme' has been used in a political sense, usually with some of the same meaning and connotations as today, since at least the mid-nineteenth century. However, the term 'extreme right' and its cognates are surprisingly recent arrivals in political science's standard vocabulary, having been regularly employed in the discipline only since the 1950s. Lipset (1959a/1963), for example, used the term very occasionally in his *Political Man* and published an article in 1959 with 'right-wing extremism' in its title given in quotation marks (Lipset, 1959b), it became conventional usage among European (except German) commentators during the 1960s, and it achieved final recognition in American political science with Lipset and Raab's (1970/1971) *The Politics of Unreason*. One reason for the slowness with which the term came to be adopted in the United States was the popularity of the alternative, and still widely used, 'radical right' (e.g., Kitschelt and McGann, 1995; Norris, 2005) in order to describe political phenomena that other present-day analysts would call 'extreme right.' Lipset had also been responsible for the introduction of the term 'radical right' into American political science, and so for its popularity during much of the following decade. It was perhaps taken from the usage in German of *rechtsradikal*. This neologism, although also postwar, can be traced back to its introduction into German in the early 1950s, probably influenced by the fact that Germany's most significant extreme-right party was then the later-proscribed *Sozialistische Reichspartei* (SRP). This designation, though sometimes also *extrem rechtsradikal*, was widely used by German authors in the 1960s and 1970s, and has only relatively recently been superseded among a majority of German political scientists by *rechtsextrem/rechtsextremistisch* (e.g., Greß et al., 1990; Jaschke, 1994); the America-based Minkenberg (1998) was an apparent exception, although he has also shown his readiness to use the word 'extremism' as a synonym for these phenomena (e.g., Minkenberg, 2009). The distinction was also a bureaucratically important one in Germany, since a purported, if casuistical, distinction between *rechtsradikal* and *rechtsextrem* was the basis on which the German *Bundesamt für Verfassungsschutz* (Federal Office for the Protection of the Constitution, BfV) justified varying monitoring and control strategies toward different right-wing formations. By the later 1990s, extreme-right activities in Germany made this distinction increasingly dubious. The translation into English of *rechtsradikal* as 'radical right' long remained peculiar to American political science; the translation given for it in the standard German–English dictionaries published in the 1970s, both British and American ones, was still 'right-extremist,' 'extreme right-wing,' or simply 'rightist'; 'radical' was introduced later into the translated meaning.

A Definition of Extreme-Right Parties

An inclusive definition of extreme-right parties has necessarily to be extensive and complex; in order to include all types of party that have attracted the designation, though not necessarily a consensus attribution by all analysts, the definition must be appropriate for such parties and movements as diverse in time and location as the American Anti-Masonic Movement of the 1820s; the Know-Nothing Movement of 1850s America; the French Boulangist Movement of the 1880s; interwar fascism in Italy and other European countries; Nazism in Germany; McCarthyism in 1950s US; Poujadism in 1950s France; George Wallace's 1968 American Independent Party (AIP); recent European examples such as the French *Front National* (FN), the German *Nationaldemokratische Partei Deutschlands* (NPD), the *Deutsche Volksunion* (DVU, which merged with the NPD on 1 January 2011), and *Die Republikaner* (REPs); the British National Party (BNP); Vladimir

 http://dx.doi.org/10.1016/B978-0-08-097086-8.93087-3

Zhirinovsky's *Liberal'no-Demokraticheskaya Partiya Rossii* (Liberal Democratic Party of Russia); the current Hungarian *Jobbik Magyarországért Mozgalom* (Movement for a Better Hungary, henceforth *Jobbik*); some of the Indian Hindu nationalist parties such as *Shiv Sena* (Shiva's Army); certain types of new Christian right fundamentalism, especially as seen in the United States within the Republican Party; and purportedly more mainstream political parties of the present such as Austria's *Freiheitliche Partei Österreichs* (FPÖ) and Switzerland's *Schweizerische Volkspartei* (SVP). The contemporary American militias are usually regarded as extreme right, but they are idiosyncratic examples not regarded as political parties, their most obvious European analogue perhaps being the militant neo-Nazi 'defense groups' of Germany and some Scandinavian countries. Although far from all analysts agree on the 'extreme right' designation for every one of these, each has nonetheless attracted such an attribution from at least a critically minimum number of historians, political scientists, or informed journalist observers. Commentators from some countries have been more ready than those elsewhere unwaveringly and without collateral justification to label contemporary examples as 'extreme right.' An inclusive definition of the extreme right has to be based on ideological features such as those below and, although each would not necessarily apply with equal emphasis and significance, or at all, to all extreme-right parties, all political scientists using this concept would understand that many or most would, at leadership or mass-support level, characterize a political party so designated:

- selective inclusion, especially within the nation and often based on preferences or assumptions about ethnic or religious similarity (which may take the form of ultranationalism, ethnocentrism, or hostility to a particular religion such as Islam or Roman Catholicism);
- selective exclusion, based on xenophobia or directed against indigenous or immigrant ethnic minorities, but also against social minorities such as homosexuals, travelers (Roma), asylum seekers, or in the past even the Masons, and to whom are denied equality and equality rights;
- racism, based on supposedly biological perspectives about racial inferiority or on the fabrication of ethnic and cultural boundaries;
- anti-Semitism, which may be both specific and directed at contemporary targets, but which may in some cases involve denying, or mitigating the scale of, the Holocaust and glorifying the deeds of the Third Reich or fascist Italy;
- a preference for authoritarian initiatives by a strong state;
- the cult of a leader figure;
- a preference for a hierarchical social order;
- antisystem, antipluralist, and antiparliamentary political perspectives;
- overt hostility to political opponents, often associated with the use, encouragement, or tolerance of violence;
- low tolerance of social change; and
- nostalgia for the past.

However, it is important to note the nature of some of the variations. For example, the Hungarian party *Jobbik* (now the country's most important extreme-right formation after uniting in 2005 with the earlier *Magyar Igazság és Élet Pártja*, Hungarian Justice and Life Party), like other east-European extreme-right phenomena, is less concerned with opposing multiculturalism and immigration and more focused on scapegoating and harassing the country's internal minorities, in particular the country's Roma minority, which comprises about 8% of its population. *Jobbik* also has the very specific irredentist aim to nullify the 1920 Treaty of Trianon, under which the country's size was greatly reduced after World War I, so placing significant Hungarian-speaking minorities in present-day Slovakia and Romania. The extreme-right parties in the latter countries, such as *Slovenská národná strana* (Slovak National Party, SNS) and the *Partidul România Mare* (Greater Romania Party), are equally keen to resist the loss of territory so implied and to oppose any granting of special rights to their country's Hungarian-speaking minority as being the thin end of the wedge toward territorial autonomy. Other countries' extreme-right parties also have concerns specific to their national situations. Israel's extreme-right parties, of which there are several, have supported Jewish settlement in the occupied territories. *Eretz Yisrael Shelanu* (Our Land of Israel) for example, was formed in 2008 to seek to prevent creation of a state of Palestine and to oppose the dismantling of Jewish settlements in the West Bank. One strand of the Israeli extreme right sought the establishment of a state of Greater Israel, normally defined as the current state of Israel and the Palestinian territories. The extreme-right *Srpska radikalna stranka* (Serbian Radical Party) aspires to a Greater Serbia, a territorial concept that has varied in extent but would certainly now include areas from contemporary Croatia, Bosnia and Herzegovina, Montenegro, and Macedonia.

Attitudes to the economy, however, offer little key to a definitional criterion, for there is considerable divergence among these parties. Some, such as those like the French FN or the British BNP that seek to have or to maintain a working-class appeal, have an economic program with strongly social-democratic elements, whereas parties like the Flemish *Vlaams Belang* (Flemish Interest, VB, till 2004 the *Vlaams Blok*) or the Swiss SVP are economically liberal and in favor of free-market initiatives.

Because definitional arguments have been such a significant component of the academic literature on the extreme right, it is relevant to elaborate this debate, which has been continuing among political scientists since at least the 1980s. Although the positions of contributing authors are individually nuanced, the crux of the argument is whether it is theoretically appropriate to distinguish between right-wing extremism (or right-wing radicalism) and right-wing populism, and indeed whether some parties are too readily labeled extreme-right when they are in essence populist and might better be described by a label including that word. The terms 'neo-populist,' 'right populist,' and 'national-populist' also occur in the literature. Betz (1994), using the label 'radical right-wing populist,' was a major contribution using the distinction, and Mudde (2007) is one of the most forthright and extensively sourced recent arguments for it. Mudde opts for 'populist radical right' as his descriptor, claiming that such parties are "(nominally) democratic, even if they oppose some fundamental values of *liberal* democracy, whereas the extreme right is *in essence* antidemocratic, opposing the fundamental principle of sovereignty of the people" (Mudde, 2007: 31 (italics in original)). However, other writers – some identified with a more overtly left-wing stance – regard such a distinction as overdone and dismiss or at least

diminish it. Minkenberg (1998: 33), for example, though using his preferred term of right-wing radicalism, merely includes the idea of populism in his definition of such radicalism, which he says "is directed against liberal democracy and its fundamental values of liberty and equality, as well as against individualism and universalism." Others dismissive of the extremism–populism distinction note that all these parties are to a greater or lesser degree tainted by exclusionism and racism. Confining this encyclopedia entry only to parties fitting a reductive definition of the extreme right would necessarily cover very few significant current examples. Moreover, some parties about whom such a definitional discussion might be held have a dual strategy – participating at least for the expedient present in formal electoral politics, while at the same time having an antidemocratic and authoritarian basis to their ideology. Such an accusation might be made against, for example, the Italian *Alleanza Nazionale* (AN), a successor and palimpsest of the earlier and incontrovertibly neofascist *Movimento Sociale Italiano* (MSI), though despite its origin the AN is classified by some political scientists as not extreme right but as having refocused to become nationalist-conservative.

If, however, there is a distinction to be made among the parties that are all, at least to those on the left, to be seen as extreme right, it is partly one of organization and style and less of ideology. The Dutch *Partij voor de Vrijheid* (Party for Freedom, PvdV) of Geert Wilders is very much the creation of its founder, as was a similar Dutch party of the early 2000s, the *Lijst Pim Fortuyn*, that briefly burned brightly but after the murder of Fortuyn was quickly eclipsed by rapid descent into schism after its electoral success in the Dutch general election of May 2002. Wilders' party, like Fortuyn's before, opposes multiculturalism and is particularly hostile to Islam, wanting to retain what it claims are traditional Dutch values against an Islamic threat. It favors gay marriage and women's rights and is, in general, socially liberal. It would be unfair to equate these parties, which many Dutch political scientists now writing about them label populist and not extreme right, with, for example, the aggressive extreme right seen in Hungary's *Jobbik* or Greece's *Chrysi Avgi* (Golden Dawn, GD), with their sometimes denied but often overt neo-Nazism, their militant wings, and their unashamedly vigilante activities against specific outgroups in their countries. Indeed, in October 2013 the leader of GD and several of its MPs were arrested and accused of leading a party that was in reality, a violent criminal organization. Nonetheless, both GD and *Jobbik* secured three seats each in the European Parliament elections of May 2014.

Extreme-Right Phenomena in the Twentieth and Twenty-First Centuries

It is useful to give a very general, if crude, periodization for extreme-right phenomena of the twentieth and early twenty-first centuries, although in each of these periods there was nonetheless a considerable variety of such parties:

- 1920–45. The era of 'classic' anti-Semitic Nazism and fascism.
- 1945–70. The era of the 'old wave' extreme right, often comprising anti-Semitic neo-Nazi/neofascist parties with a yearning for the 'classic' era (e.g., Germany's SRP or Italy's MSI), but also nostalgic anticommunist movements (e.g., McCarthyism).
- 1970–2000. The era of the 'new wave' extreme right, appealing particularly on a basis of xenophobia and racism against ethnic-minority immigrant groups and asylum seekers.
- 2001–present. The era of increased globalization that has seen the emergence of new dynamics of the extreme right such as Islamophobia and the global financial collapse since 2008, including the effects of the Eurozone crisis since 2009.

This periodization is not perfect and there are anomalies. McCarthyism, for example, was a movement within the Republican Party rather than a party in its own right and it lacked the vigorous anti-Semitism of 'old wave' extreme-right parties. The American AIP anticipated the issues of the 'new wave' extreme right. However, this periodization is a useful heuristic device for discussing theoretical approaches to the analysis of these parties.

Theoretical Approaches to Explaining the Extreme Right

Fashions in political science toward the analysis of the support of extreme-right parties have not been constant. While it is important not to exaggerate these changes, it is true that research in the 1950s and into the 1970s, conducted on the vote for Nazism (the *Nationalsozialistische Deutsche Arbeiterpartei*, NSDAP) and on 'old wave' postwar parties, was especially concerned with answering questions about the partisan origins and social bases of these examples of extreme-right support. Lack of any individual-level data on voters for the NSDAP led to the use of different combinations of aggregate data in a substantial body of research about Nazism's partisan origins and social base. The consensus that emerged from the comprehensive research in this tradition has accepted the case for considerable social variety in the NSDAP's later support. Postwar parties for whose support there existed survey data were frequently analyzed in the first instance in terms of the social categories to which they particularly appealed. Ideological and attitudinal dispositions toward the extreme right were not ignored, of course (especially not by research drawing on perspectives in *The Authoritarian Personality* (Adorno et al., 1950)), but they were not always treated as the principal explicandum; indeed, many authors (e.g., some of those writing about McCarthyism in *The Radical Right* (Bell, 1963/1964)) simply imputed motive. Researchers working on parties that have emerged in the 'new wave' era have been more inclined to recognize that most extreme-right parties draw from a variety of social sources and have given greater attention to the attitudinal, psychological, and contextual bases of such support. The disproportionate support for many 'new wave' extreme-right parties among certain economic and demographic groups has been recognized, but it has not been a central focus of theorizing about them.

In giving an overview of the theoretical perspectives toward extreme-right parties, it is essential to distinguish between the pre-World War II and postwar cases. Many of the interbellum parties played major political roles, especially so, of course, in

the cases of Italy and Germany. Even in countries where such parties did not achieve power, they often had substantial impact upon national politics during the 1930s (as in France or The Netherlands). On the other hand, in the postwar period extreme-right parties, though not without some important effects upon the content of political agendas, have not usually achieved actual governmental office – significant exceptions being Italy briefly in 1959 and intermittently from the mid-1990s, Austria in 2000, Slovakia in the 1990s and after 2006, as well as the problematic case of contemporary Switzerland in the light of the metamorphosis of parts of the SVP toward the extreme right. Spain, a fascist dictatorship till 1975, is a special case.

Most theoretical analyses of the period of the interbellum extreme right focused on German Nazism and Italian fascism. Some influential perspectives came from self-avowed Marxists and, though incorporating views about the social base of these movements, attributed to them a particular role in the balance of class forces. Perhaps, the more subtle of these Marxist perspectives were those by Gramsci, who used a concept of Caesarism, and by Trotsky and Thalheimer, who drew Bonapartist analogies and regarded fascism as a resort by capitalists to perpetuate their interests in a situation of class stalemate between the proletariat and capital. Postwar Marxists have sometimes resurrected such perspectives in looking at Italian fascism and Nazism and have even sought to apply them to postwar movements, but, to most analysts, these approaches are no longer relevant. Instead, the great majority of political scientists writing about the 'old wave,' 'new wave' and present-day extreme right have sought, albeit in varying ways, to focus on the social situations that may produce extreme-right sympathy and behavior.

A widespread feature of numerous theories of both the 'old wave' and 'new wave' extreme right is to see them as supported by those who in some way have suffered, or see themselves to have suffered, from social change. This theorizing may take the form of predicating status loss (e.g., Hofstadter and Lipset on McCarthyism in Bell, 1963/1964), or disorientation as a result of social strain (e.g., Parsons also in Bell, 1963/1964), or a reaction against the growth of postmaterialist values (e.g., Ignazi, 2003), or material loss due to processes of modernization or globalization (e.g., Heitmeyer et al., 1992; Scheuch and Klingemann, 1967). Theories with a social-psychological basis, as by those who have applied perspectives derived from *The Authoritarian Personality* and the Frankfurt School to 'old wave' and 'new wave' parties, also assume a resistance to, and intolerance of, certain types of social change. 'New wave' extreme-right parties since the 1970s, because in many cases they have made racism and xenophobia the principal basis of their appeal, have particularly attracted theorizing seeking to explain the presence of such attitudes among individual voters and in certain groups of voters.

Writers on this subject in the more recent period, while not neglecting these theories of the circumstances of individual susceptibility to the appeal of the extreme right, have rather shifted the explanatory focus more to what the literature calls 'opportunity structures' – the contextual situations, whether political or social, that foment or assist the rise and persistence of extreme-right phenomena. That has certainly been the emphasis in the literature on the most controversial and publicized examples of the recent extreme right, whether the most militant cases of the genre like *Jobbik* in Hungary and GD in Greece or the 'softer,' arguably populist, ones such as the PvdV in The Netherlands. Extreme-right parties emerge and – a separate issue – succeed in sustaining themselves only in certain particular conditions. The analytic consensus is that there has to be an electorate attracted by the appeal made by the party, usually on some one particular issue on which feelings are strong (such as hostility to multiculturalism); that there is widespread disillusion with established parties, the cause of which may be a range of issues or may be their failure successfully to address in the eyes of those attracted to the extreme-right party the concerns raised by the issue; that electors so affected feel powerless and neglected as a result; and, critically important, that there is a party leadership seen to have credibility and competence to promote the cause concerned. All these dynamics may also contain the key to whether the party can sustain itself or whether its momentum will falter. If their chosen party disappoints because little of the discontent that sustained its rise is seen to have been assuaged, or if one or more of the established parties successfully convinces one-time supporters of the extreme-right party that the established party has adopted policies to address their concerns, the success of the extreme-right party can be short-lived. If the extreme-right party's leadership loses the aura of competence or is revealed as corrupt, or if the extreme-right party descends into factionalism, its support is equally likely to decline. There are numerous historical examples of these processes. The success of Britain's National Front of the 1970s was thwarted by the take-over by the Conservative Party of a sanitized dilution of its appeal and then later by its internal schism. The German REPs in the 1990s lost support as the party descended into schism. The Dutch Centrumdemocraten, also in the 1990s, undoubtedly suffered from leadership deficiencies. On the other hand, a leadership has sometimes been sufficiently convincing to sustain the party, despite attempts by other parties to coopt the issues that concern it. Again, there are numerous historical examples: the FN in France and, more recently, the PvdV in The Netherlands.

Social Bases of Extreme-Right Parties' Support

Even within the undoubtedly generally eclectic support base of the prewar extreme right there were concentrations in specific circumstances, and the same is true of extreme-right phenomena of the more recent period, though political scientists have nonetheless offered generalizations about the social base of such parties. Lubbers et al. (2002) gave a comprehensive pan-west-European analysis of extreme-right support – albeit including some parties that would be regarded by Mudde and others as merely radical-right populist rather than extreme right – and from this certain general conclusions about such support in the mid-1990s can be drawn: individual such supporters tended to be male, younger, less educated and, in terms of employment status, manual, self-employed, or unemployed – findings that were consistent with research in the 1980s about such examples as the FN and the German DVU. Norris (2005)' analysis – including non-European parties

and parties not extreme right on the exclusionary definition – gave party-specific breakdowns and showed that an analysis such as the one of Lubbers and his colleagues, which did not differentiate between individual parties could lose some details of difference. The male preponderance, however, is one finding that is almost universal and extends to activists as well as voters. However, there are examples, such as the Austrian FPÖ and the New Zealand First party, whose support in the 1990s was especially from older rather than younger voters. Not all extreme-right parties are supported disproportionately by the less educated, the Israeli extreme right being one of the exceptions, as more recently has been electoral support for *Jobbik*. The class base of the extreme right is by no means uniform – in some countries the disproportionate contribution of the self-employed is significant but this is not universal, and nor is disproportionate support from manual workers or the unemployed. Hungary and Israel stand out as examples of the extreme right's sometimes appealing particularly to more affluent strata. One problem with these generalizing approaches using many examples is that they are largely fixed to a single point in time and are less suited to detect evolutions in such support. For example, the center of gravity of support for both the FN and the FPÖ evolved during the 1980s and 1990s from nonmanual to manual voters, as these countries' social-democratic parties' traditional hold on the support of manual workers slipped; the FPÖ also became disproportionately attractive to much older voters as its support increased during the 1990s.

Any niceties of variation in social base assume a lesser explanatory importance from the repeated findings that, irrespective of individual social characteristics, it is attitudinal dispositions that are by far the better predictors of extreme-right support: such attitudes are typically racist or antiimmigrant/antiasylum-seeker opinions or antisystem attitudes toward the mainstream parties. However, even in the first case there are exceptions – attitudes to immigration do not particularly distinguish FPÖ supporters from voters for other Austrian parties and, among the some of the east-European examples, attitudes to immigration are less significant than those toward indigenous ethnic or linguistic minorities.

Alternative Forms of Extreme-Right Movement

Although this article is about extreme-right political parties, it would leave a wrong emphasis not briefly to note that there are other types of extreme-right activity. Many countries have seen forms of the extreme right that have not participated significantly in formal electoral politics. In many countries there have been demonstrations and marches designed by the most committed activists of the extreme right to demonstrate their 'street presence.' For example, until 2005 the small German town of Wunsiedel in northeast Bavaria suffered an annual Rudolf Hess Memorial March by neo-Nazis, this being the town where Hess' remains were then buried. Other extreme-right movements have their own 'pilgrimage' locations. The annual IJzerbedevaart (Pilgrimage of the Yser) in the Flemish city of Diksmuide, intended to celebrate peace and to focus on Flemish autonomy, attracted the unwelcome attention of European neo-Nazis for a number of years until they were banned; the attraction to them was that the site had been the location of collaborationist ceremonies during World War II. The English Defence League (EDL), claiming to be merely anti-Islamist, may be cited as a further example of an alternative form of extreme-right movement. Except for a desultory link in 2011 to a very small British extreme-right party, the now-defunct British Freedom Party, it has eschewed formal political involvement in favor of media appearances by its leaders and an on-the-street militancy using marches in areas with high levels of Muslim population.

Since at least the 1970s, there have been yet more forms of extreme-right activity. The 'skinhead' phenomenon has been associated with the extreme right in a number of countries, including France and Germany. Related, and also significant for the culture of parts of the extreme right, has been a White Power music scene as an activity that from early on was able to transcend national frontiers. Another arena has been a certain type of support of particular football clubs in several countries, including Great Britain, Germany, Italy, and The Netherlands; in Italy the clubs AS Roma and SS Lazio are especially notorious. The most extreme manifestations of this behavior – anti-Semitic and racist chanting and giving the Nazi salute – have been largely stamped by the stewarding authorities in northern Europe, but they remain an issue among certain clubs in southern and eastern Europe, where they sometimes also emerge in support for national teams.

A yet further forum for extreme-right activity and mobilization has been the Internet, which has also facilitated the easy transcendence of national borders by the extreme right and, for example, brought a range of extreme-right American material, protected by the First Amendment in the United States, within easy reach of European extreme-right supporters. Indeed, the popularity of the Internet for the dissemination of extreme-right material and its consumption by an unspecified number of users raise the question whether the customary method used by social scientists to measure the strength of extreme-right support – numbers of votes in elections and numbers of identified activists in known extreme-right organizations – is now outmoded. The number of lone but Internet-connected extreme-right supporters – individually exemplified most dramatically by the case of the Norwegian terrorist and murderer Anders Behring Breivik – is undoubtedly far greater in some countries than the numbers of voters and activists.

The Tendency of Extreme-Right Parties to Schism

Extreme-right parties frequently exhibit distinctive organizational characteristics in comparison with mainstream political parties. The former have a particular tendency to split, and contain strong schismogenetic features. This is sometimes because of personal animosities between leaders, who are often psychologically disposed to be authoritarian and are intolerant both of different perspectives and also of rivals. Because of the variety of ideological appeals offered by extreme-right parties, their leaderships and supporters often have a mixture of social origins and this too can lead to divisive differences over minutiae of ideology (a characteristic shared with extreme-left movements). Extreme-right parties, particularly those in the

postwar 'new wave' period, have exhibited a remarkable tendency to fracture. In France, Germany, Great Britain, The Netherlands, and Switzerland, to name only some examples, the indigenous extreme right has had a history of division and internal dissension. Indeed, many of the apparent electoral successes in the 1980s and 1990s by extreme-right parties foundered on the organizational collapse of the elected legislative grouping, something that was a particular feature of the German extreme-right parties, the REPs and the DVU. The British BNP – apparently on the crest of a breakthrough at the beginning of the 2000s in some locations in northern England where it appealed to local anti-Muslim sentiments – became mired in internal dissensions and suffered a loss of credibility.

The Future of Extreme-Right Parties

Even 10 years ago it was possible, viewed from a democratic pluralist perspective, to be relatively sanguine about the future of the extreme right. In few countries was it a well-supported phenomenon. Even in countries where its support was stronger, such as France or Flanders, the political system had excluded it from governmental participation, at least at the national level, although in the 1990s the FN, for example, had a few successes in the south of France in obtaining municipal control and extreme-right parties in some other countries had similarly enjoyed some local government successes. However, the FN generally glorified in its pariah status; a faction wanting to seek accommodations with mainstream right-wing parties had caused a damaging split in 1998, but it was the breakaway *Mouvement National Républicain* of Bruno Mégret wanting such a rapprochement that failed electorally against the FN when their respective popularities were put to an electoral test. True, the FPÖ in Austria had been part of a national coalition government for a short period, the Slovak SNS had been small part of a coalition government in the 1990s, and the Swiss SVP, part of the multiparty coalition that had governed Switzerland since 1959, was turning in some cantons increasingly into an extreme-right party and increased its support and national influence in doing so. However, the accession to power of the FPÖ had led to revulsion and boycott by some other countries in the European Community (as then called) and had significantly damaged the country's international reputation. Even the SNS had, and still has, trouble reaching the country's five-percent electoral threshold. Parties in other countries, such as Australia's One Nation party, had burned briefly but then guttered and died – 'like bees: once they have stung, they die,' in Hofstadter's memorable and much-quoted aphorism about the American People's Party.

A decade and more later, the state of the extreme right is rather different. The dynamics that became important in the period after 2000 show little sign of diminishing in intensity. Rising and persistent unemployment in many countries in Europe and the Americas, combined with the likelihood of long-term economic recession or depression, offers the breeding ground for extreme-right mobilization. The decline, continuing a process that in many countries can be traced back to the 1970s, in committed mainstream political partisanship, especially of working-class attachments to social-democratic parties; the general rise of electoral volatility; the evidence in many countries of increasing disenchantment with mainstream politicians and political parties: all these are factors that provide a pool of less attached voters who may be attracted to the extreme right. A pool of such voters has always existed in most countries, as has an underlying, if otherwise dormant, propensity to some form of extreme-right mobilization. The issue for the likelihood of future success for extreme-right politics is whether that pool is becoming critically larger.

The extreme right has had various levels of success in securing parliamentary representation and has been assisted in this in some countries by a wholly or partly proportional franchise system. In an assembly such as the European Parliament its presence has had little impact. However, in The Netherlands the PvdV and in Denmark the *Dansk Folkeparti* (Danish People's Party) achieved significant policy influence by their support for minority center-right coalition governments. In Hungary, where the mainstream right party *Fidesz* (*Fidesz – Magyar Polgári Szövetség*, Hungarian Civic Union) governs with a smaller right-wing party and has a comfortable parliamentary majority, it has nonetheless been influenced on several policy positions by the presence of *Jobbik* to its right on the political spectrum. Even majoritarian electoral systems have not wholly frustrated the extreme right; in France, where in the 2002 Presidential election the success of Jean-Marie Le Pen's first-round 16.9% of votes was somewhat soured for him by more than 82% of voters opposing him in the second round, the FN succeeded in securing seats in regional elections, though its success in more local elections was otherwise patchy. Increasing support for extreme-right parties is not inexorable; electoral support for all the longer-lasting examples has ebbed and flowed according to the vicissitudes of leadership, policy and credibility, though it is parties such as the FN and VB with more capable leaderships and better organizations that have been deft enough to survive periodic downturns of fortune.

Perhaps the greatest longer term dynamic of the extreme right in some Western countries is Islamophobia, which has fueled support for new extreme-right parties such as those in The Netherlands, has provided an issue on to which older extreme-right parties such as the French FN have latched, and has provided the pretext for street-level militancy in a number of countries (the EDL in Great Britain, for example). As long as there is a view, even a minority one among a small number of indigenous Muslims, that the presence of some Western countries in the Islamic world is illegitimate, Islamist reactions to this will be a potent source of Islamophobia in those countries and then of extreme-right benefits from this.

The issues are rather different, however, for the extreme right in eastern and southern Europe; such parties have so far been qualitatively different from those elsewhere. The trajectory of these extreme-right parties is unclear, partly because their dynamics are contested and not all countries in this region have equally significant such parties. Some parties have ultranationalist and often irredentist concerns, having emerged from long-held resentments that arose between 1919 and 1949, and are therefore seen by some as a type of revival of the interbellum extreme right. Others are shaped by the structures and attitudes induced by Leninist state socialism between 1949 and 1989. Others were simply products of the chaos after the post-1989 dissolution of the Soviet Bloc and may increasingly come to resemble west-European extreme-right parties. Quite

how each will evolve, and so what danger to democracy it will pose, is a quandary.

Political Parties: Manifestoes

Ian Budge, University of Essex, Colchester, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Manifestoes are defined and described physically. Their unique standing as the only authorized expression of collective party preferences gives them a central place in guiding policy voting and effecting the party mandate. Their strategic role in election campaigns causes them to be written in a particular way: stressing party concern with their own issues and downplaying rivals' issues, and avoiding specific policy stands. Nevertheless, manifestoes indicate what priorities parties will pursue if they get into government, and in this sense form a unique link between electors' preferences and government actions.

Introduction

Manifestoes or platforms are the programs usually issued by parties in campaigning for elections. They give an analysis of current problems and future developments endorsed – uniquely – by the party as a whole through its formal procedures. As such they are crucial to the operation of the democratic mandate: the idea that parties are chosen by electors for government on the basis of the competing policies they present. Only in the manifestoes can such competing policies be found, since the manifesto is generally the only policy statement endorsed officially by the party as a whole – in the election or indeed at any other time. The unique standing of the manifesto as a statement of official party policy renders it to be useful practically, as a guide to the media and (indirectly) electors, about what the party stands for; and also crucial analytically, as the best indicator of what the party's collective preferences are. It is, however, a coded statement designed to win over votes. Hence its interpretation has to be based on assumptions about how parties compete for votes, which are described below.

The Nature of the Manifesto

In the UK, United States, and some continental European countries, manifestoes are published by the party as booklets at the official start of the election campaign. There have been clear physical changes in their appearance and length during the postwar period. They have become markedly longer and noticeably glossier. Starting out as badly printed, unillustrated pamphlets immediately after World War II, they have in some later cases approached the size of books. A more recent tendency is to have a plethora of glossy photographs, colored charts, and figures to reinforce and break up the text, which itself is headed by and interspersed with sound bites.

Elsewhere, practices in regard to the publication of election programs differ. In France, programs have sometimes been published commercially as books, which have attained the best-seller list! In Scandinavia and Canada, they have at times been split as separate pamphlets addressed to women, youth, workers, and other demographic groups. In Japan, they are widely diffused as summaries of interviews with the party secretaries, published in the leading mass circulation newspapers. In Australia and New Zealand, they do not even get into print, but are substituted by an hour-long television address from the party leader – the content of which is organized along conventional lines, and so covers much the same range of topics broken into the same kinds of sections as in the United States and UK.

These variations may reflect a growing realization that most electors do not read party programs, even if they are pushed through their door. Instead, they get an impression of them from media discussion. Media presenters, on the other hand, read programs very carefully, using them to start debates and confront party spokespeople if they try to pull back from concerns expressed in the document. In this sense, the manifesto constitutes a policy equilibrium point for the party which is set at the outset of the campaign (Budge, 1994).

Reading the document casually, however, one might be hard pressed to discover much policy content at all. Until recently, specific promises have been limited and confined mostly to pledges on peripheral problems where the party knew it could deliver with some certainty if it became (part of) the government (Rallings, 1987). Most of the text discusses general trends and developments under such headings as Youth, Unemployment, the Economy, and so forth. Depending on whether the party is in government or opposition, it describes the situation in optimistic or pessimistic terms, sometimes going into the historical achievements of the party or stressing the importance of the area.

Rarely, however, is the text more specific than this. The manifestoes of competing parties do nonetheless succeed in presenting quite contrasting diagnoses of the current situation – one painting a glowing picture of free enterprise surging ahead amid general prosperity, another pointing to growing social inequalities and the pressing need for government intervention. Without further information, one could not even be sure if they appeared at the same election or at different ones!

Electoral Competition and the Manifesto

The reason for structuring election programs in this way is to be found in the view party strategists take of competition for votes. In line with Riker's (1993: p. 105) 'dominance principle,' electors are seen as overwhelmingly endorsing one 'obvious'

line of policy in each area: cutting taxes, strengthening law enforcement, extending social provision, and so forth. Particular parties, because of their record and ideology, are associated with each favored line of policy. If you want to cut taxes you will not vote Socialist but you will if you want to extend welfare.

For the parties, competition thus consists in getting 'their' issues – the ones on which they are associated with the popular line of action – on to the agenda. To do this, they need to emphasize the importance of such issues compared with those which favor rivals. Their manifesto advances this process by talking a lot about 'their' party issues, ignoring areas 'belonging' to rival parties. As the task is to convince media and electors of these issues' importance, the manifestoes can ignore fine details of policy in favor of general discussion – a tactic which, conveniently, does not tie parties down to specific actions when in government.

The view of party competition, which emerges from analyses of manifestoes (Robertson, 1976: Budge and Farlie, 1983: Petrocik, 1996) is thus one in which relative emphases on different issues substitute for direct confrontation over differing policies on the same issue. This is not to say, however, that parties are not putting forward different programs of government. Parties that talk a lot about taxes mean to cut them and parties discussing welfare mean to extend it. Manifestoes are about priorities between tax, welfare, and other areas, even if the other side to the debate – cutting services or increasing taxes – goes unstated.

Using Manifestoes in Political Research

The way manifestoes are written makes them relatively easy to analyze quantitatively. By counting sentences or words into different policy areas and percentaging them out of the total to standardize for length, one can contrast left-leaning and right-leaning parties and even characterize their attitudes within different policy areas (Klingemann et al., 2006). Word counts of electronic texts can be performed easily by computer programs, opening up new possibilities of research once the techniques are better validated. Sentence counts have been carried out manually for all significant parties in 51 countries over the postwar period, from the time of the first democratic election (Budge et al., 2001; Volkens et al., 2013).

Given the manifestoes' standing as the sole authorized statement of party collective policy preferences, such analyses can give an exact picture of parties' ideological progression and shifting policy stances over the postwar period. This is illustrated in **Figure 1**, which traces the US Democrats' and Republicans' left–right movement over the postwar period. (Left–right is measured by adding all percentage mentions of 'rightist' issues and subtracting from this the total percentage mention of 'left-wing' issues (Budge et al., 2001: pp. 21–24).)

Figure 1 shows first of all that Democrats and Republicans take up the standard left and right positions assumed by Socialist and Conservative parties in other countries. The validity of interpreting US party competition in left–right terms is supported:

Figure 1 Right–left movement of American parties 1945–2008 as shown in their platforms.

Figure 2 British parties' support for social conservatism, estimated from manifestoes 1945–97.

1. by the way in which contrasts between the parties mirror the historical record – for example, far apart at the 'Goldwater' election of 1964, closer in 1992 with Clinton's famous move to the right;
2. by the high correlation between presidential platform positions and the relative 'liberalism' of subsequent presidential policy (McDonald et al., 1999). (This finding incidentally illustrates the usefulness of comparing manifesto commitments with actual policy as a method of checking out mandate theory (McDonald and Budge, 2005: 107).)

Figure 1 also serves as a check on Downsian theories of party competition, which predict policy convergence between parties as both seek to position themselves near the median elector (Downs, 1957: pp. 110–117). Clearly this expectation is not fulfilled as the US parties always maintain their ideological distance from each other, even where they converge to some extent, as in 1992. Their patterns of movement are explained better by the 'saliency' theory, where parties are stuck with their traditional issue positions and can act strategically only by varying the emphasis they put on them (Budge et al., 2010).

Such changes can be monitored for the separate issue areas by seeing what percentage of sentences are devoted to them in the manifesto at different elections. Figure 2 traces British parties' concerns with traditional morality and law and order ('social conservatism') from 1945 to 1997. The Conservative Party generally appropriates this area, where it presents itself as the defender of 'family values.'

Linking Manifestoes to Election Change

As well as supplementing historical analyses of party change, such 'maps' of party movement can also be related to voting behavior. Instead of estimating party positions indirectly by asking electors about them, we can actually study the effect of a party's strategic adjustments on electors' perceptions and subsequent voting decisions. This extends the possibilities of linking such phenomena as 'revisionism' to electoral reactions, to see if it actually has the effects claimed for it (Evans and Norris, 1999: pp. 87–101). Methodologically, one can marry textual analysis to survey research to deepen the insight provided by both.

Linking Manifestoes to Government Action

Manifestoes mediate between electors' preferences – expressed by voting for the closest party – and government actions as mirrored in expenditure or legislation. As well as investigating what impact they have on electors, the priorities in the manifesto can be related to government policy outputs. Research has shown them to be quite closely linked (Budge et al., 2012: pp. 178–193) thus upholding 'mandate' ideas that the party or parties in government have been popularly authorized to carry through their program and indeed have a responsibility to carry it through.

This moral commitment is reinforced by two other characteristics of manifestoes, which give them an impact in government.

1. Manifestoes reaffirm party ideology, applying it to specific policy areas. Thus most party representatives, who belong to a party in the first place because they subscribe to its principles, actually want to carry out manifesto commitments regardless of electoral considerations.
2. The manifesto is often the only worked out program the party has for government. Even where coalition partners make a policy agreement about what to do, the separate party manifestoes feed into it. For practical reasons of coordination and planning in government therefore, the manifesto is an indispensable document.

Overall Role and Significance of Manifestoes

Cynicism about the extent to which parties keep their promises, and hence about the significance of the manifesto which contains them is easy. The election program has often been seen as a 'mere piece of paper' forgotten immediately the party gets into government. The research cited above, however,

shows that the manifesto deserves to be taken more seriously, both by voters and political analysts. Parties are responsible, both in maintaining consistency with previous policy and in carrying it out in government. This would hardly be so, if they just shifted policies around in response to electoral expediency. What Figures 1 and 2 show is considerable stability in the positions taken by the only policy document which parties issue collectively. This renders it an invaluable source for studying party intentions and preferences, and a good guide to what they will do in government.

Political Protest and Civil Disobedience

Dennis Chong, University of Southern California, Los Angeles, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Political protest refers to a multitude of methods used by individuals and groups within a political system to express their dissatisfaction with the status quo. Although protest can be registered through voting, letter writing, campaign contributions, participation in interest groups and political parties, and other traditional means, the term more commonly refers to those kinds of mass political activism that occur outside of conventional parliamentary channels, such as demonstrations and marches, labor stoppages, boycotts, and other methods that combine communication and persuasion, direct action, and noncooperation with political, economic, and social institutions.

Civil disobedience is a particular form of political protest that is marked by the deliberate violation of the law with the express goal of correcting a perceived injustice. Action that would now be regarded as civil disobedience has been a regular feature of social protest throughout history even though the term itself, attributed to an 1849 essay by Henry David Thoreau, is a relatively recent creation.

Political protest refers to a multitude of methods used by individuals and groups within a political system to express their dissatisfaction with the status quo. Although protest can be registered through voting, letter writing, campaign contributions, participation in interest groups and political parties, and other traditional means, the term more commonly refers to those kinds of mass political activism that occur outside of conventional parliamentary channels, such as demonstrations and marches, sit-ins, blockades, labor stoppages, boycotts, and other methods that combine communication and persuasion, direct action, and noncooperation with political, economic, and social institutions.

Much social science research on political protest has concentrated on explaining organized, sustained forms of mass collective action such as social movements. A social movement consists of an array of organizations and individuals who share a common identity and agenda of social and political goals, and who are regarded as a collective entity by other political actors. Social movements typically pursue their goals by mixing protest actions with conventional political strategies, such as lobbying, litigation, public education, and electoral mobilization. Discontented groups often resort to direct action when they are denied equal access to conventional means of participation or when such avenues are regarded to be ineffectual or inadequate for registering the intensity of their grievances.

Protest as an Assurance Game

Mass protest movements often can be represented by a type of strategic interaction known in game theory as an 'assurance game,' in which individual decisions to contribute are contingent on the mutual cooperation of a sufficient number of people. Supporters of a movement therefore try to coordinate their decisions with those of other activists, participating when it appears that the movement has enough popular support to be politically effective, but not otherwise. Such decisions, however, typically have to be made with considerable uncertainty about both the intentions of other individuals and the prospects of the movement as it develops.

Consider how these sources of uncertainty alter the calculations of activists. Each individual has to determine how the costs and benefits of participation vary according to the aggregate level of participation. Costs include the opportunity costs and risks of political activism, while benefits include both collective benefits (e.g., policy changes) that go to all supporters of the movement whether or not they participate, and selective benefits (e.g., material rewards, social esteem) that go only to those who participate. Let us assume that the benefits of participation increase, while the costs decrease, with the size, N, of the movement. Therefore, at low levels of N, the movement generates few, if any, benefits and is extremely costly for individual contributors, making abstention the preferred alternative. If the movement is able to attract more widespread support, several favorable developments occur: its prospects for success improve, selective incentives become more salient, and the costs of participation decline with the growing safety of numbers. In accordance with the assurance game, I assume that there is some threshold level of participation, $N = n'$, above which cooperation provides net benefits.

Estimates of the threshold value for participation will vary among group members depending on their assessment of the prospects and benefits of collective action, and estimates of the probability that there will be a sufficient number of cooperators will also be unsettled. Obviously, much depends on the responsiveness of the government or other petitioned party to the demands of the movement. Someone who thinks that collective action has little chance of succeeding will set very high levels for n'; in the most pessimistic case, n' will exceed the size of the group seeking change – in other words, even total cooperation will be assumed to be futile. To further complicate matters, not only will an individual be uncertain in his or her own mind about these parameters, but he or she will also know that others are uncertain about them too, and that everyone is aware of each other's uncertainty. Given this individual calculus, a number of inferences can be drawn about the

resources, strategies, goals, and political conditions that will be required to coordinate and organize mass social protest.

Leadership

Prior to organizing, people suffer diffuse grievances and contemplate various means to address them. Leadership is therefore necessary to develop a common understanding of the problems people face and to provide convincing arguments in favor of collective action. All analysts of social movements point to the importance of having an ideology that interprets people's circumstances and offers prescriptions for action. The task of leadership is to use such ideological appeals to create a group identity among those who are discontented and to train the energies of group members on a set of targets and solutions to their problems. Leaders therefore help to define the assurance game for others by persuading them of the promise entailed in collective action. In addition to defining the game for others, leaders help mightily to solve it by constituting, in effect, the critical mass that instigates the growth of collective action.

Community

Knowledge of the calculations and intentions of fellow group members is, of course, alleviated when collective action is built out of existing organizations and community relationships. The sociological literature is rich with examples of social movements capitalizing on existing social networks of individuals with common interests and goals.

Groups in general are more readily mobilized than individuals. Individuals in groups – bonded by a distinct ethnicity, race, or social status; ties of friendship and kinship; and common membership in religious, fraternal, social, and political clubs, associations, and organizations – have greater solidarity and are in closer communication than groups that are not constrained by similar functional and social linkages. Solidarity and affection, in turn, go hand in hand with the establishment of personal obligations and exchange relationships. Members of these preexisting networks have reputations to protect, respect, and affection for each other, and reliable information about the preferences and probable behavior of others.

Mass Communications

Modern communications technology can compensate for weak grassroots organizations and expand the popular base of a social movement by facilitating the rapid transmission of information. While small groups can be coordinated through meetings and face-to-face interaction, the coordination of large masses of people in disparate locations depends on central sources of information transmission. Through the electronic media, people can learn about the plans of the movement to initiate new campaigns, the size and impact of demonstrations in distant cities, how authorities are responding to collective action, whether third parties are sympathetic or hostile to the struggle, and other relevant information that updates their evaluation of the movement's prospects. Various means of communications not only inform interested parties, but also convey information that the recipient will interpret as common knowledge based on his or her assumption that access to this information is widely shared.

A key factor behind the massive size of the 1989 upheaval in Eastern Europe is that people were extremely well informed and aware of political developments in their own country and abroad. With the aid of modern telecommunications, the opposition movements were able to coordinate strikes, demonstrations, and other activities. For example, one of the most effective ways that Solidarity leaders in Poland transmited information was to provide foreign radio networks with details about their strike activities, which would then be broadcast in news reports throughout the country. When the Czechoslovak opposition gained access to the radio and television waves, it was able to provide updates on the progress of the movement to parts of the country beyond Prague. Moreover, through print, radio, and television, people throughout Eastern Europe were able to stay apprised of developments in the West and in the Soviet Union. It was easy to learn from the media about Gorbachev's support for the upheaval in Eastern Europe, his plans for reform in the Soviet Union, and the consequences of those reforms, namely, competitive elections and the development of an independent national legislature.

Tacit Coordination Using Cultural Resources

Overt leadership solves the coordination problem; but leadership can often be identified and eliminated by the authorities trying to prevent collective action. To reduce the need for explicit communication, activists can capitalize on famous locations, significant anniversary dates, focal events such as deaths and funerals, and other cultural signposts when staging mass demonstrations and protests. A striking feature of the revolutions in Eastern Europe was the manner in which the opposition movements took advantage of salient historical precedents to coordinate their activities. Much of the protest activity in Hungary, Poland, and Czechoslovakia in 1989 occurred at the same sites where earlier protests had been held. There were obvious parallels between the processions organized by the opposition in Budapest in 1989 and similar processions staged during the 1848 and 1956 Hungarian Revolutions. In Czechoslovakia, the demonstrators conducted their rallies at the symbolic Wenceslas Square, the historic setting for most of the nation's greatest political events. Similarly, Leipzig's famous tradition for opposing authority, dating from the Protestant Revolution and extending through the Peasants Rebellion, the 1848 revolution, the workers' uprising in 1923, and the sympathy protests for the Prague Spring, may help to explain why the mass demonstrations that brought down the regime in East Germany were initiated in that city before diffusing to the rest of the country. All of these examples illustrate how history and tradition can supplement overt leadership and formal organizations in coordinating mass political activism.

Demand and Supply

Participation in collective action may begin with the belief among individuals that enough pressure can be applied to win

concessions from the opposition. Sooner or later, however, collective action will have to produce real dividends to sustain the motivation of activists. Therefore, in addition to trumpeting the potency of collective action, the leaders of a movement will try to wrest concessions from their adversary as quickly as possible. Doing so establishes a level of proficiency and success that reinforces their followers and makes the movement attractive to others. Notable successes spur a bandwagon of new participants to join based on their revised estimates of the prospects of the movement. In addition, concessions establish the responsiveness of the authorities to political pressure.

The premium that is placed on continual success gives rise to an evolution of tactical strategies over the course of the movement based on what succeeds. Tactics that work in forcing the opposition to supply concessions will become popular, while those that prove ineffective will be abandoned. Each innovative tactic will lose its appeal within a movement once its effectiveness is reduced by the tactical countermaneuvers of the opposition.

Leaders of collective action must therefore devise a continuing series of novel tactics in order to retain their followers and maintain the leverage of the movement. During the American civil rights movement, for example, several innovative tactics, such as the bus boycott, sit-in, and freedom ride, grabbed the spotlight at different times. After a new tactic was introduced, the following months of activity in the civil rights movement tended to be dominated by copycat campaigns in other locales around the country. The popularity of various tactics used over the course of the civil rights movement rose and fell according to their success in gaining media attention, provoking southern authorities, and extracting meaningful concessions.

Political Opportunities

The incentive structure of the assurance game also shows how fluctuations in demands for social change will be linked to the disposition of the agencies capable of supplying such change. A sympathetic government or a government that is expected to be responsive to popular demands will obviously encourage collective action. It seems reasonable, for example, to suppose that extremely repressive countermeasures in the early stages of the demonstrations in Eastern Europe in the late 1980s could have halted the popular movements there. Once compliance with government ideology dissolved at both the private and public levels, the only restraints on mass dissent were the twin threats of internal repression and Soviet intervention. The two methods of repression were not independent, however. State resistance and countermeasures were evident in Poland, East Germany, and Czechoslovakia in the early stages of these movements; but once it became apparent that the Soviet Union would not interfere – except to send encouraging signals about its nonintentions – the option of internal repression also became limited. By the summer of 1989, fears that either form of repression would occur had diminished greatly even in the more hard-line states of Czechoslovakia and East Germany. What is remarkable, nevertheless, is the speed with which the publics in Eastern Europe sized up current events and seized the moment when it became apparent that the Communist system was ready to collapse.

The Power of Social Media

The advent of social media has changed the technology of political protest, accelerating its dynamic in ways that are predictable from social movement theories. Facebook, Twitter, and YouTube have been used extensively to inform and coordinate participants in the 2010–11 revolutions in Tunisia and Egypt, and in subsequent popular protests against socioeconomic inequality in Western nations.

Social media reduce the costs and practical barriers to coordination by facilitating communication that can help to solve collective action problems. The value of social media has been to allow people to discover the extent of discontent in society and the willingness of people to engage in political protest. Online resources can be used to strengthen the development of networks and social movement communities that are built on face-to-face interactions and ongoing relationships.

Social media take on greater importance in authoritarian societies that do not enjoy freedom of the press, speech, or assembly, and where the government closely monitors organized groups and frequently jails its leaders. The availability of new means of communication that can bypass these barriers is a significant development that has weakened the ability of governments to control and contain the diffusion of information. Virtual forums of communication can be safer sites of discussion than in-person gatherings. Citizens can learn of government abuses, inadequate social conditions, and the disaffection felt by other citizens. Social media can therefore both reveal and coordinate widespread discontent, which are essential stages in mobilizing political protest.

The technology also affects the strategies and methods of social protest and government responses to dissent. The ability of citizens to document government reactions to protest can also place constraints on government misconduct, thereby lowering the cost of protest. Mobile phones with picture and video capabilities allow 'citizen journalists' to record and publicize protests and to bypass state-censored coverage. Through content created on social media, political activists are able to bring outside pressure to bear on the governments facing popular unrest. Such international support for demonstrations and protests against unpopular regimes can also strengthen resolve among the demonstrators.

Social Media in the Arab Spring

Political protests in Tunisia in 2010–11 succeeded over a repressive government that maintained tight controls over the media. Online social networks allowed elite activists to circumvent government censorship and build a digital network that became the foundation for the 2010 uprising. Following a dramatic triggering event (the self immolation of a fruit vendor), social media allowed transmission of information to international media, especially Al Jazeera, despite efforts of the government to limit reporting on internal dissent. Al Jazeera had limited capacity to cover events within the country, especially in more remote areas; web activists stepped into the breech and served as journalists by providing video to Al Jazeera showing atrocities committed by government police forces that was then broadcast to Tunisian citizens.

Images and videos circulated on the Internet reduced the legitimacy of the Ben Ali regime in Tunisia. Reports of the abuses of the regime in response to the protests served as a catalyst that broadened the social bases of support for the uprising. Social media were critical in publicizing the size of the protest demonstrations and in creating expectations about the magnitude of future protest gatherings, thus promoting safety in numbers and reducing the fear of protest. Individuals learned about future protest events online and could also anticipate that these events would be well attended based on online responses to announcements of future protests. The information that opponents of the government obtained from the Internet increased their confidence that the Ben Ali regime would be brought down by the protests.

The collapse of the Ben Ali government in the face of mass protests gave inspiration to Egyptians to organize similar protests in early 2011 against their government. The Egyptian Revolution was over quickly – 18 days from start to the removal of President Hosni Mubarak – but the social and organizational foundation of the movement was laid in preceding years. The April 6 youth movement was formed online several years earlier during an effort to organize support for a nationwide strike. The creation of a Facebook page around the April 6 strike led to over 70 000 individuals joining the group. The movement took advantage of a political opportunity created in 2005–06 when the George W. Bush administration pressured Mubarak to conduct multiparty elections. This opening allowed individuals to organize a loose coalition of activists around the goal of preventing Mubarak from handing power to his son. At the same time, the Internet was becoming more readily available in Egypt and became an important tool of political communication that substituted for face-to-face meetings.

Dissenters harnessed the new technologies associated with social media to publicize police brutality and social and economic problems. An emerging group consciousness grew around these grievances, especially among university graduates who suffered from high unemployment rates. Popular protests arose over poor living conditions, inflation, low wages, and state repression. The event that instigated the 2011 protests leading ultimately to the removal of Mubarak was the killing by Egyptian police of a blogger, Khaled Saeed, who had posted incriminating video of police misconduct. A Facebook page publicizing the killing and showing pictures of Saeed's body became a focal point for the expression of grievances against the Mubarak regime.

Protest organizers used Facebook and Twitter to organize the initial protest on 25 January 2011. Facebook was a platform for sharing ideas and plans, causing the government to try to block Internet access in the country. The size of the crowds in Tahrir Square grew rapidly over the course of the protests, but it was critical that the first day of protest drew an overwhelming crowd because this was a powerful signal of the amount of discontent among the public that encouraged others to join. Online communications were coupled with conventional means of spreading information through leaflets and word of mouth to reach individuals without the Internet access. Social media informed people and strengthened ties and commitments among them that were critical to sustaining protests in the face of opposition.

Social Movements Now and Then

Social media have facilitated the rapid diffusion of symbols and methods across nations, as well as solidarity for common causes. The Occupy movements in Western cities in 2011 were in many ways inspired by the Egyptian Revolution. The original announcement of the idea to 'occupy' Wall Street was carried in an Adbusters poster with a Twitter hashtag that went viral over the Internet.

Some of the appeal of recent social protests against economic inequality in Western nations has been their spontaneity and lack of hierarchy, discipline, and leadership. The protests have marshaled and aggregated discontent about the economy, government, social services, equality, and political representation. Not everyone who participates will be or needs to be equally committed to the goals of the movement. When large numbers of protesters are joined in opposition to a regime, the presence of weakly committed individuals may, nonetheless, make a crucial difference in communicating the size and breadth of social support for the movement. For example, Internet protests in China that are held together by loose online ties have often been sufficient to instigate a government response to mass reactions to unjust outcomes or decisions.

However, the elements of successful social movements are not fundamentally changed by new technologies, even if those technologies provide additional resources that can be employed in contemporary protests. Organizations may have become less central to the mobilization of people with the advent of social media, but weakly structured movements that do not have clear leadership also exercise less control over the participants and the demands and agenda of the movement.

Movements still require leadership, strategy, and interpersonal and organizational networks to establish goals and to ensure discipline and continued participation. Inexperienced activists without prior participation in protests may be less committed and less likely to sustain their participation in the face of government opposition or repression. The spontaneity of the Occupy movement throughout Western nations in 2011–12 and its themes of economic equality and corporate responsibility enjoyed considerable short-term success, but there was no agenda for achieving policy changes that may have sustained the movement.

Civil Disobedience

Unlike protest marches, picketing, and other kinds of legal protest, civil disobedience is a particular form of political protest that is marked by the deliberate violation of the law for social purposes. Civil disobedience is not merely conscious law breaking, but rather it is law breaking with the express goal of correcting a perceived injustice. Action that would now be regarded as civil disobedience has been a regular feature of social protest throughout history even though the term itself, attributed to an 1849 essay by Henry David Thoreau, is a relatively recent creation.

The act of civil disobedience is fundamentally an act of political protest because the noncompliance is intended to convey a message of discontent to the government, media, and

public. The acts of defiance are typically overt, public acts aimed at marshaling collective opposition to unjust or unconstitutional laws and policies. Civil disobedience is not restricted to protests over laws and public policies, but is also employed against the practices of private institutions such as corporations and universities, as occurred, for example, in the divestment campaign on American university campuses in the early 1980s, which pressured universities (both private and public) to cut their financial ties to companies that conducted business in South Africa in an effort to bring an end to apartheid.

Forms of Civil Disobedience

Within this broad conceptualization, civil disobedience can emanate from different motivations and assume a number of forms. Civil disobedience can be active or passive, direct or indirect. An individual can either actively commit a prohibited act or passively refuse to conform to a prescribed action. For example, an antiwar protester may destroy his draft card or, alternatively, he may refuse to register for the draft. Both actions qualify as civil disobedience because the protester intentionally violates the law as an expression of his opposition to the war, knowing the legal consequences of his actions. Thoreau himself engaged in a form of passive civil disobedience when he chose to register his opposition to the institution of slavery by refusing to pay the Massachusetts state poll tax.

Civil disobedients often break laws that are unrelated to the law or policy they are protesting. For example, peace activists who disrupt operations at defense laboratories are not protesting laws against trespassing, but are using civil disobedience to dramatize their opposition to nuclear weapons. Supreme Court Justice Abe Fortas objected to the indirect use of civil disobedience on the grounds that it would give license to people to break any law they wished in the service of a goal that they perceived to be nobler. But few scholars have subscribed to this restriction because, on many issues, there is no feasible direct method to engage in civil disobedience. There may, for example, be no direct method by which activists can use civil disobedience to protest the government's foreign policy or its failure to pass laws addressing issues of inequality and poverty.

A narrower definition of civil disobedience would exclude illegal actions taken by individuals who do not accept the constitutionality of the law they are violating. By this definition, an activist who breaks the law by setting fire to the American flag is *not* engaging in civil disobedience if he believes that his actions are protected by the First Amendment, but a flag burner who accepts the constitutionality of a law against flag burning *is* engaging in civil disobedience. For the purpose of defining civil disobedience, however, it may be unnecessary to make such a distinction based on the activist's frame of mind, because the crucial assumption underlying civil disobedience is that the law being broken is generally viewed to be valid by those in authority, so the actions of the civil disobedient are generally viewed to be illegal. Therefore, both flag burners are committing civil disobedience in the sense that they are breaking what is generally understood to be the law in an effort to change it, and the main difference between them is whether they are appealing to the courts or to the executive and legislature for remedial action.

Although Thoreau assumed that 'civil' protest would be conducted in an orderly and peaceful fashion, scholars disagree over whether civil disobedience is necessarily nonviolent by definition. Some commentators insist that civil disobedience must be nonviolent, or else it cannot be distinguished from rebellion, rioting, and other types of violent direct action. The two individuals who are most responsible for the association of civil disobedience with nonviolence are Mohandas Gandhi (see e.g., Gandhi, 1961) and Martin Luther King, Jr (see e.g., King, 1964). Indeed, contemporary understandings of civil disobedience have been substantially shaped by the mass campaigns for equal rights organized by Gandhi in South Africa and India, and by the King in the United States.

Both Gandhi and King possessed the extraordinary combination of political 'savvy' and unwavering moral and spiritual commitment to the philosophy of nonviolence. In his teachings, Gandhi insisted that civil disobedients must scrupulously obey laws that are unrelated to the target of the disobedience campaign and submit themselves to the punishment of the state for breaking a law they believed to be unjust. Civil disobedients do not flee or resist arrest, for in accepting penalties for their actions, they bring attention to the injustice they wish to correct and arouse the sense of injustice in others. Gandhi's concept of *satyagraha* or 'truth force' refers to the moral conversion of one's adversary. In their quiet suffering, civil disobedients demonstrate their honor and integrity and their capacity to differentiate between just and unjust laws.

King regarded Gandhi as his mentor and shared his belief that the purpose of civil disobedience is to persuade the state and its citizens that an existing law violates a higher moral principle. Violence, therefore, must be avoided because it potentially undermines the communicative intent of civil disobedience. Adherence to nonviolence, on the other hand, indicates that one bears no malice or hatred for one's opponent. Like Gandhi, King believed that the ultimate goal of a campaign of nonviolent protest is to achieve a new moral understanding with one's opponents. Nonviolent resistance works, not by defeating and humiliating the opponent, but by winning the opponent's empathy and friendship.

Justification of Civil Disobedience

In addition to disagreements over what kinds of actions qualify as civil disobedience, there is debate over the circumstances in which civil disobedience can be justified. Civil disobedience raises issues about the nature of authority, obligation, and consent in society. The practice originates from the idea that a person must be true to his conscience and that he is not obligated to submit to the laws or commands of the state when they violate his conception of justice. Civil disobedience therefore assumes both a right to individual freedom and the existence of a natural law that takes precedence over civil law.

Philosophical discussions of the justification for civil disobedience generally fall between legal and moral individualism. In justifying civil disobedience, it is necessary to accept that there are standards against which governments can be evaluated, and citizens have the right to exercise such judgments. Few would argue that the law must always be obeyed; and similarly, few would contend that obeying the

law is entirely a matter of individual judgment about what is morally right and wrong. One extreme supports despotic governments, while the other suggests anarchy. Whether civil disobedience undermines respect for the law is a matter for empirical inquiry. The penalties for breaking the law are usually sufficiently great that it is unlikely that people will engage in civil disobedience unless they are intensely motivated by a sense of injustice.

But do the moral criteria for civil disobedience reside only in conscience? Or are there intersubjective criteria that permit rational assessment of the morality of a law or policy? Without such objective criteria, we are in danger of every individual invoking arbitrary subjective criteria for disobeying different laws. We invite moral anarchy unless there are some agreed-upon criteria for evaluating whether a law or policy is unjust or immoral. At a minimum, the civil disobedient must be able to demonstrate that the law or policy violates principles of welfare, equality, or justice. The law or policy must be shown either to do more harm than good, to distribute benefits unequally, or to operate without the consent of certain groups. Legal methods of petition to change the law must be tried first, and the activists must grant the same rights of civil disobedience to others who believe that another law is unjust. Some would argue that the civil disobedient must also have a reasonable chance of overturning the law. According to these normative criteria, only those who believe in reciprocity and adhere to a sophisticated set of general rules of political conduct can rightfully be said to be engaged in justifiable acts of civil disobedience.

Effectiveness of Civil Disobedience

What are the mechanisms that make civil disobedience effective in practice? Gandhi recognized that civil disobedience could not be effectively employed for a global, distant goal such as national independence, but had to be used for specific, local issues on which the opposition had the power to compromise and make concessions. True to form, civil disobedience campaigns led by Gandhi were most successfully applied in local disputes concerning such issues as land revenue assessments and mill workers' wages, in which small numbers of close knit, disciplined protesters were united by their interest in the issue and capable of conforming to a norm of nonviolence.

In theory, if civil disobedience is to work through persuasion, then the protesters must invoke principles or values that are shared by a large proportion of the population. In practice, however, the preferences that are converted are more likely to be those of the spectators to the conflict than those of the adversaries of the protesters. A small number of disobedients can seldom, by their actions alone, render a law inoperative, but they may be able to disrupt the social order sufficiently to draw public attention to their grievances. Although Gandhi believed that the suffering of protesters in jail would apply pressure on the government, he also recognized that the state's use of violence would serve the interests of the protesters by influencing third parties who were witnesses to the conflict. British repression of Indian dissenters confirmed to onlookers that the British ruled by force and not through the consent of the Indian population. Similarly, in the course of the civil rights movement, it was the contrast between the nonviolent protesters and the violent response of the southern police that helped to galvanize public opinion and mobilize federal government intervention in support of racial equality.

In response to a campaign of civil disobedience, the defenders of the status quo must decide whether to offer concessions to the protesters or to escalate the conflict by using force or summoning the power of the state. It is the threat of continued disruption of the normal operations of business and government that 'persuades' the targets of the protest to negotiate with the activists and to yield to their demands. During the civil rights movement, the early success of direct action campaigns in some southern cities aimed at forcing businesses to provide equal treatment to blacks made it easier for similar campaigns to succeed elsewhere, because businesses foresaw the normal course of these protests and sought to cut their losses sooner rather than later. There is little evidence that the attitudes of white southerners were converted by direct action; indeed, the attitudes of many were hardened by the confrontational tactics of the movement.

Civil disobedience thus rarely works through persuasion and attitude change alone, but also depends significantly on pressure and coercion. Actions that are aimed at transforming preferences may leave attitudes unchanged, but still be effective at promoting social change because the opponents are pragmatic enough to calculate that they are better of making concessions than dealing with the disorder created by continual protests. Civil disobedience in this respect resembles a pragmatic tactic within a repertoire of potential strategies that are available to a protest group rather than an option that is resorted to only when the conventional channels of participation have been exhausted.

Abstract

Political psychology is an interdisciplinary field of inquiry concerned with the analysis of political thought and behavior of individuals within politically organized communities. Survey, experimental, and qualitative research examines political behavior at the individual and the collective level, in the general public and among political elites, and as formal and informal processes of political participation. Key topics in political psychology include political beliefs and values, cognitive processes in political decision making, political communication, media effects, political rhetoric, international conflict, racism and prejudice, ethnic identities, and collective action.

Political Psychology

Political psychology is an interdisciplinary scientific field of inquiry concerned with the study of political processes from a psychological perspective. At the most general level, political psychology is concerned with political thought and behavior of individuals within politically organized communities. Research in political psychology examines political behavior at the individual (e.g., decision making) and at the collective level (e.g., collective action), it concerns processes occurring in the general public (e.g., public opinion) and among political elites (e.g., psychology of leadership), and it relates to formal (e.g., voting) and informal (e.g., community involvement) processes of political participation.

The boundaries between political psychology and the various fields of inquiry it draws upon are blurred. The discipline uses theory and methodology derived from cognitive, personality, social, developmental, and organizational psychology, from research traditions within political science interested in political behavior and decision making, from sociology, education, public opinion, and communication research. It is therefore difficult to demarcate without ambiguity the boundaries of research in political psychology from studies in the respective neighboring disciplines.

Its interdisciplinary nature has been an essential feature of political psychology since its beginning. During the short history of the discipline, the two disciplines have often existed side by side, for example, when either psychology (personality analyses, political cognition) or political science (political behavior) defined the main paradigms under investigation. Yet, the question of how to articulate and integrate the different methodologies, worldviews, and epistemologies associated with psychology and with political science remains a recurrent concern. Some approaches may be accused of 'too much psychology' (neglecting political, organizational, and systemic explanations) while others may be seen as 'too much political science' (using simplified models of psychological capacities and motivations and ignoring how citizens actively make sense of political situations). Nevertheless, much research has successfully integrated the two disciplines by creating original and innovative research paradigms in political psychology.

In the next section the historical and institutional context of political psychology is briefly outlined, followed by summaries of the most common fields of investigation of political psychology.

The Context of Political Psychology

A Short History of Political Psychology

Political psychology has a long past, but a short history. While the origins of the interest in the relationship between psychological processes and political organization can be traced back to ancient Greece, the philosophy of enlightenment and nineteenth century social and political science (with widespread interest in crowd psychology, for example), political psychology as a field and later as a discipline emerges in its own right after WWII. McGuire (1993) distinguishes three phases in the short history of political psychology: in the 1940s and 1950s, researchers were concerned with behavioral pathology and the impact of personality on political processes, inspired by psychoanalytic and behaviorist theories. During the 1960s and 1970s, scholarly interest turned toward political attitudes and voting behavior, largely based on newly available survey data and statistical techniques that allowed, for example, investigating the impact of political campaigns on attitudes and voting behavior. During the 1980s and early 1990s, the field was largely focused on political cognition and individual decision making, thereby reflecting the cognitive trend observable in other behavioral sciences as well. The citizen was represented as a limited information processing machine that was nevertheless able to take good enough decisions based on various cognitive heuristics. While the first handbook of political psychology was published in the early 1970s (Knutson, 1973), it is during this period that a number of textbooks explicitly devoted to the discipline of political psychology appear, all clearly marked by the cognitive approach to political psychology (e.g., Iyengar and McGuire, 1993; Lau and Sears, 1986).

Since the mid-1990s, the field has grown significantly and has become ever more diversified. Today, no single approach can be considered as dominant or organizing the field as a whole. 'Classical' research topics on personality profiles of leaders, psychodynamic explanations of political behavior, cognitive approaches to political decision making, or analyses of prejudice and racism in political processes continue to

attract the attention of researchers. Political psychology has been thriving during the past two decades and an evident sign of this trend is the increasing number of new books published under the header of political psychology, including edited books (Borgida et al., 2009; Monroe, 2002), a textbook (Cottam et al., 2010), a reader (Jost and Sidanius, 2004), and a handbook (Sears et al., 2003; Huddy et al., 2013; for the second ed.). Moreover, reflecting the trend toward integration of biological and social processes, political behavior is increasingly explained with neurological and genetic models (Marcus, 2012).

The Societal Turn

In 1993, McGuire was correct in predicting that a fourth wave of political psychology would concern research on intergroup relations, social change, and ideological beliefs. These new topics seem to reflect a deep change that has occurred in political psychology since the mid-1990s. Much like social psychology, political psychology has moved toward closer scrutiny of societal issues related to power relations between groups, political legitimacy, and civic participation. One may speculate that this changing focus is the result of changing historical conditions of the recent past, including the breakdown of cold war certainties in 1989, growing economic inequalities in contemporary free market societies, an increasing number of grievances and claims by minority groups, tense political polarization in many Western countries, and the various terrorist attacks that have marked recent history.

This theoretical expansion of political psychology is associated with a significant geographical development of the discipline. Since its beginning as a modern scientific discipline, political psychology has largely been defined through North American research. Accordingly, until the mid-1990s, non-American political psychology was virtually inexistent. This situation of American predominance has now radically changed: the single most important development in the recent history of the discipline is the growing interest for and the massive expansion of research in political psychology in non-American countries, in particular Europe. This is evidenced with increasing attendance from European researchers at political psychology conferences, with the number of papers published by European researchers, and with the founding of the new *Journal of Social and Political Psychology* in 2013 that explicitly seeks to attract a broad international audience. More importantly, this move toward Europe has also sparked new theoretical developments, for example, critical political psychology that focuses on collective action, globalization, and the migration experience (Kinnvall et al., 2014; Tileagă, 2013) and a social representations approach to political psychology that proposes dynamic, contextual, and normatively determined analyses of political behavior (e.g., Howarth et al., 2014).

Methods in Political Psychology

The field relies on a variety of methodological approaches. Survey research is privileged by political scientists to study research questions requiring correlational and longitudinal analyses, for example, dynamics of public opinion and voting behavior, political values and ideological beliefs, and cross-cultural differences in political attitudes. Experimental approaches are more often used by psychologists to test causal models, for example, concerning cognitive processes in rational choice decision making. The recent shift toward research concerned with societal issues has brought qualitative approaches to the forefront of political psychology, including discursive and rhetorical approaches that enrich the traditionally positivist worldview of political psychology with a more constructivist epistemological orientation.

Institutionalization

While research in political psychology has existed since the 1940s, proper institutionalization of the discipline began in 1978 when the International Society of Political Psychology was founded by Jeanne Knutson from the University of California, Los Angeles (UCLA). In 2013, the association had about 800 members many of which attend the Annual Meetings that have been held every year since then, with rotating locations between North America, Europe, and other locations around the globe. A summer academy in political psychology for young scholars is linked to the Annual Meetings. The society publishes Political Psychology, the respected quarterly flagship journal of the discipline, and, starting in 2014, the annual series Advances in Political Psychology.

Moreover, a 3-week summer school in political psychology is organized by Stanford University, and major associations such as the American Political Science Association and the European Consortium for Political Research have active political psychology sections.

Graduate and undergraduate courses under related titles are taught in leading universities around the world, and many American universities offer degrees in political psychology, mostly in political science departments. While Queens University, Belfast, is the first European university to offer a complete political psychology program, many other universities have graduate programs that run under different labels but nevertheless offer curricula closely related to political psychology (e.g., various social psychology programs).

Overview

In this text, some of the most emblematic research in political psychology will be presented, but many important topics are necessarily left out (e.g., biological, genetic and evolutionary approaches, deliberation and network research, emotional and motivational approaches, psychobiography, conflict resolution). Research in political psychology can be organized into three major categories of research, and the presented approaches are deemed to represent some of the key characteristics of each of these categories.

Individual-level processes are concerned with personality profiles of citizens and political leaders, with political beliefs and values, with the role of socialization and individual development in the formation of political beliefs, and with the examination of cognitive processes in political decision-making. A second strand of research is concerned with *political communication*, including media communication, political

rhetoric, and constructivist approaches. A third field of research examines *group-level processes* in political thought and behavior, including international relations and conflict, the role of racism in politics, group identities and cultural diversity, and collective action and social change.

Individual-Level Processes

Personality Profiles of Citizens and Political Leaders

Personality is understood as being composed of traits, needs, motives, and self-conceptions that predispose individuals to relatively stable and consistent patterns of political thought and behavior. Hitherto referred to as 'temperament' or 'character,' personality profiles have been amply used to explain the behavior of both political leaders and followers. Psychodynamic approaches were dominant in the early days of research on personality, referring to unconscious drives and mechanisms. The *Authoritarian personality* syndrome (Adorno et al., 1950) was developed in the aftermath of WWII to explain mass submission to political authorities, aggressive behavior against minority groups, and uncritical endorsement of totalitarian ideologies. This pioneering study was further developed with research on dogmatic personalities that leads individuals to be more receptive to rigid, closed-minded belief systems (Rokeach, 1960). But it was not until the 1990s that the 'Big five' became an almost consensually accepted general system to describe personality traits through five dimensions (extraversion, agreeableness, conscientiousness, neuroticism, and openness to experience). Much research since then has examined the relationship between personality traits and political orientation, showing, for example, that openness to experience is generally associated with left-wing support, whereas conscientiousness is more likely to lead to support for right-wing parties. Other studies have shown persistent links between extraversion and openness to experience and various forms of political participation, including voting, attending meetings, campaigning, and signing petitions. Another personality dimension concerns general needs and desires, differentiated by McClelland (1985) into the three basic motives of achievement, affiliation, and power. Research in the motivated social cognition tradition, in turn, distinguishes between epistemic, existential, and relational needs, and showed that political conservatism is associated with the epistemic need for cognitive closure and the existential need for safety (Jost et al., 2003).

Studies on *personality profiles of political leaders*, in turn, suggest that history is at least partly shaped by leaders' idiosyncratic ways of perceiving and interpreting social reality (e.g., distortions, confirmatory bias), private memories (e.g., war experiences in childhood), personal goals (e.g., power orientation), cognitive styles (e.g., rigidity), and emotional reactions to stress (e.g., low tolerance for stress). Autocrats' grandiose self-conceptions, fears, and obsessions also play a role in their strategies to maintain power. The major difference with large-scale personality studies is that leader personalities can generally only be assessed with indirect methods, including psychobiography (accounting for leader personality through an analysis of childhood experiences), content analyses of formal and informal speeches, and personality ratings by individuals close enough to leaders to judge them.

Political Beliefs and Values

Political beliefs differentiate individuals and groups according to their ideological orientations and political preferences. Debates revolve around the question of the structure of beliefs systems. In many studies, a single dimension (conservatism vs liberalism or left- vs right-wing orientation) is used to differentiate individuals, but it becomes increasingly clear that one-dimensional models are no longer adequate to account for the heterogeneity and variation of political beliefs. There is today a large consensus that at least two independent dimensions are required, one organized around social and cultural issues (traditional morality vs cultural freedom), and the other one around economic positioning (egalitarianism vs meritocracy). An important set of studies has, for example, analyzed the complex and context-dependent relationships between *Social Dominance Orientation* (assessing attitudes toward group-based inequality) and *Right-Wing-Authoritarianism* (the ideological equivalent to the authoritarian personality described above).

Values play also a central role as individual-level organizers of political judgments and behavior. Schwartz's (1992) theory of the human values system paved the way for the systematic analysis and comparison of the impact of values on political behavior. Typically, left-wing political orientations are associated with values of universalism and benevolence, whereas right-wing positions are related to the values of self-enhancement, power, achievement, and conformity.

The origins of political beliefs and values can partially be traced back to *socialization* during childhood and early adult years. There is increasing evidence that early learning of politically relevant information, including political beliefs, intergroup attitudes (e.g., racism), and social identities (e.g., national identity) remain stable across time, giving rise to considerable political continuity over an individual's life course (Sears and Brown, 2013). There is also support for the hypothesis of preadult family transmission, with studies showing substantial parental transmission of political party identification to adolescent children. Nevertheless change in sociopolitical behaviors, attitudes, and opinions still occurs in adult years, as a function of new contingencies and changes in the wider sociocultural environment.

Cognitive Approaches to Political Decision Making

Political decision making is one of the most important research domains in political psychology, and rational choice theory is the most commonly used theoretical framework to explain decision-making processes. Basic assumptions of (normative) rational choice theory are that individuals have a coherent set of preferences, gather the necessary information to reach an informed decision, evaluate alternative actions, and choose actions that are optimally related to their beliefs and values. Such decisions are expected to further individuals' self-interest and are therefore deemed rational. However, the rational choice approach is confronted to a paradox, since research has amply shown that in practice political decision-making virtually never follows these principles. People lack consistency in

their opinions, use information incorrectly, are overconfident in their own choices, fail to adapt existing evaluations in light of new information, draw unwarranted conclusions from insufficient data, and express prejudiced opinions. Moreover, political decision making, in particular voting, is only weakly related to actual self-interest.

Following the implausibility of a 'full' rational choice model, researchers have developed models of 'bounded' rationality that are based on similar assumptions as rational choice theories, but that recognize individual and contextual variation in decision-making processes and outcomes (Kahneman, 2011). To compensate limited information, cognitive biases and lack of motivation, bounded rationality models such as behavioral decision-making theory describe a number of cognitive strategies that help individuals to make 'good enough' decisions: simplifying the decision task, selectively filtering new information, interpreting information as a function of preexisting ideological predispositions, and making sense of political issues through evaluations of social groups involved in the decision (e.g., beneficiary groups of welfare programs). Individuals also refer to opinions of others to make up their mind, for example, by relying on expert judgments, by socially validating their opinion through comparisons of opinions with those of relevant others (informational influence), or by aligning their opinion with the perceived majority opinion in their community to avoid marginalization (normative influence). Finally, they may also defend the interest of their group (collective self-interest) rather than only their individual self-interest.

Nevertheless the amount of *factual knowledge* citizens possess does make a difference for the decision-making process (Delli Carpini and Keeter, 1996). High levels of knowledge are, for example, likely to increase the alignment of one's decision with one's beliefs and preferences. Yet, while many studies highlight low levels of political knowledge and lack of political sophistication of citizens, the actual implications of this general lack of knowledge remain debated.

Political Communication

Media Communication

Communication between citizens and between citizens and political leaders is another key topic for political psychology. Research on mass media has analyzed how media shape political outcomes by directing the public's attention to major issues (agenda setting) and by describing those issues as a function of the communicator's interests (framing effects). *Agenda setting* shows how successful the media are in determining what citizens 'think about,' based, for example, on research showing nearly perfect correspondence between the issue priorities of the public and news organizations. Research on *framing* in turn has shown that individuals are highly sensitive to the way policies are described and survey questions worded, and that even minor changes in the labeling of political alternatives can produce strong effects on public opinion. For some, such findings challenge the validity of democratic opinions, since opinions appear to be highly volatile as a function of irrelevant pieces of information. Antidotes to framing effects are deliberation, expertise, and exposure to competing frames (Druckman, 2004). Nevertheless, framing effects can also be viewed as part and parcel of everyday political reasoning, since people necessarily rely on peripheral cues to form an opinion. Framing has also a strong strategic dimension, since messages are deliberately framed by political elites (parties, interest groups) to move opinions in the direction of their interests. Extremist groups, for example, may be portrayed as exercising their right to freedom of expression, or they may be described as a risk for public safety. Similarly, poverty may be explained with individual behaviors or with political choices, thereby altering attributions of responsibility and ultimately affecting political decisions.

Constructivist, Critical, and Rhetorical Approaches

The growing number of constructivist and critical approaches to political psychology can be seen as one of the most important theoretical developments in the recent history of the discipline. These approaches offer a conceptual alternative to the causal models characterizing a majority of studies in political psychology (Tileagă, 2013). In a constructivist perspective, political thought and behavior is contextualized within the social and cultural environment.

This constructivist perspective can be exemplified with the social representations approach that has recently entered political psychology. This approach explores the processes by which citizens come to a shared understanding of political issues and how this shared understanding relates to their possibilities for political action (Elcheroth et al., 2011). Communicating knowledge creates communities of belief that transform individual opinions into social representations, that is, into knowledge shared and debated by members of the group. Such shared knowledge (e.g., awareness of excessive social inequalities) then becomes the basis for political action, both individual (e.g., voting) and collective action (e.g., mass demonstrations). In line with constructivist principles, social representations do not just reflect social reality but they constitute that social reality, and sometimes change the nature of that reality. Hence, political thought and behavior is as to large extent shaped by what people think others are thinking (meta-representations).

Given its focus on the social context that produces representations, a social representations approach highlights the role of power relations in the communication and dissemination of representations between individuals and between groups. Political participation, for example, can be conceptualized as the power to construct and convey particular representations over others (Howarth et al., 2014). In this view, the 'framing' of concepts is a sign of the inescapably contested nature of political concepts such as freedom, equality, democracy, or justice. Such abstracts notions are open to debate and dispute and much of political action and discourse can be viewed as competitive attempts to impose specific interpretations of political concepts, events, and situations consistent with the actor's political goals. Opposing sides may, for example, refer to a same concept that is assumed to appeal to the people: for the Democratic Party in the United States, the Affordable Care Act (Obamacare) brings 'justice' to the American people, whereas for the Republican Party only the repeal of the same law would do so. Quite clearly, the interpretations of 'justice'

vary wildly in these two rhetorical perspectives. A social representations approach thus examines the construction of legitimate and dominant political knowledge, and the strategies used to marginalize and silence alternative ways of knowing and being. While this type of power is typically afforded to high-status groups who have the power to construct what is 'real' or 'true,' social representations nonetheless allow for resistance and agency through the active reappropriation of existing knowledge.
